The semiotic study of visual signs overlaps considerably with the study of mental imagery within psychology. An image is defined simply as a mental picture of objects, events, feelings, actions, situations, and ideas (real or otherwise). Images allow us to recall events, refer to them in various ways, and to generate hypothetical scenarios of situations or conditions that we may not even have actually experienced. Mental images are substitutes for real things, allowing people to recall, plan for, and predict things (Kosslyn, 1983, 1994). But these are not monolithic. Individuals differ widely in their abilities to construct images and use different aspects of imagery. For example, some people are better than others at moving objects around in their heads. They can visualize, say, the letter N changing into a Z when rotated to a certain point. Others have great difficulty in carrying out such imaginary rotations. People imagine faces and voices, locate imaginary places, scan game boards (like a checker board) in their minds, arrange furniture in a room, design a blueprint, and so on in similar, but significantly differentiated ways (Kosslyn, 1983, 1994).

Psychological studies have shown that images also vary along cultural lines. When asked to visualize a triangle or a cat, people living in the same culture will come up with very similar mental pictures of the two referents. These isomorphic images are known as 'cultural prototypes' (for the concept of 'prototype' in psychology, see Rosch, 1973, 1975, 1981, Rosch and Mervis, 1975, Taylor, 1995). The triangle that people living in Western culture typically imagine is an equilateral one, because it is the type of triangle that is perceived as the prototypical or basic form. It is the one that is perceived to be exemplary or representative of all triangles. Obtuse-angled, right-angled, and acute-angled triangles are perceived to be subtypes of the equilateral triangle. Similarly, the image of the cat that comes to the mind of subjects living in Western culture is that of a household cat, because it is the most typical in that culture.

Images are not generated only by visual perception. They can be elicited through other sensory and affective modalities. These modalities can be easily experienced by imagining such things as: (1) the sound of thunder, (2) the feel of wet grass, (3) the smell of fish, (4) the taste of toothpaste, (5) the sensation of being uncomfortably cold, (6) the sensation of extreme happiness. The image that comes to mind in the case of (1) has an auditory quality to it, (2) a tactile one, (3) an olfactory one, (4) a gustatory one, (5) a bodily one, (6) an emotional one. Moreover, images are not elicited solely by sensory modalities; they can be abstract, fictitious, or narrative. As an example of an abstract image, think of *love*. The image that this concept evokes is tied to some personal experience, such as the expression of a face in love. A fictitious image is something that can be made up in the imagination. An example of a fictitious image is a 'winged

table.' Although no such thing exists in real life, we nonetheless have no problem imagining it. Finally, a narrative image is one that unfolds like a story. For example, we recall encounters with people in narrative ways, with different images representing different episodes of the encounter in a storylike fashion.

Image Schemas

Ferdinand de Saussure (1857–1913), one of the modern-day founders of semiotics, used the word *image* in two senses in his theory of the sign (Saussure, 1916: 16). He defined a signifier (such as a word) as a 'sound image' and its signified (meaning) as the 'conceptual image' that the word calls to mind. Recent work on the conceptual imagery associated with verbal forms has shown that Saussurean images are 'schematic' (Johnson, 1987; Lakoff, 1987; Lakoff and Johnson, 1980, 1999). This has led to the development of *image schema* theory within linguistics (*see* **Cognitive Linguistics**). Image schemas are defined as unconscious mental outlines of recurrent shapes, actions, dimensions, orientations, objects, etc. Although they are unconscious, their 'reality' can be easily ascertained by prompting subjects in specific ways. For example, if someone were asked to explain the expression 'I'm feeling *up* today,' it is unlikely that he or she would describe an image involving an upward orientation. However, if the subject were asked 'How far *up* do you feel?' 'What do you mean by *up*?' etc., then the subject would start visualizing the schema in question and provide appropriate description of the image schema.

According to Lakoff and Johnson (1980, 1999), such schemas guide the formation of common concepts. As an example, consider the image schema of an impediment. An impediment is something, such as a wall, a boulder, another person, etc., that blocks forward movement. We know from actual experience that we can go *around* an impediment, *over* it, *under* it, *through* it, or else *remove* it and continue on. On the other hand, the impediment could successfully impede us, so that we would have to *stop* at the impediment and *turn back*. All of these actions can be easily imagined in the mind. These are derivatives of familiarity with actual impediments. Now, as Lakoff and Johnson have persuasively argued, the very same image schema is used unconsciously to form abstract concepts. It is the psychological reason why we say such things as: 'We *got through* that difficult time'; 'Jim felt better after he *got over* his cold'; 'You want to *steer clear of* financial debt'; 'With the bulk of the work *out of the way*, he was able to call it a day'; 'The rain *stopped* us from enjoying our picnic'; 'You cannot *go* any *further* with that idea; you'll just have to *turn back*'; and so on and so forth. Image schemas are, clearly, crucial in abstract concept-formation, linking bodily and perceptual experiences.

Figure 1 Using three lines to represent different figures.

Visual Representation

Drawing pictures, making charts, sketching diagrams, and the like are such common things that we hardly ever realize what they involve. They are part of an innate semiotic competence that allows people to utilize a sensory modality, such as sight, to represent the world through signs.

Visual representation has been studied under various rubrics both within semiotics and in other disciplines. The focus in semiotics is on the use of elemental signifiers (forms) such as *points, lines,* and *shapes* (Dondis, 1986) that are combined in various ways to represent figures. Consider, for instance, what can be accomplished with three straight lines. These can be joined up in specific configurations to represent by resemblance a triangle, the letter 'H', or a picnic table (among other things) (see Figure 1).

The use of visual signifiers in this way is called, more specifically, iconic representation (*see* **Iconicity: Theory**). If arrowheads are adjoined to lines, they can be used as signifiers to represent movement and direction (see Figure 2).

This is an indexical use of signifiers for spatial and orientational representation (*see* **Indexicality: Theory**). Shapes are visual signifiers designed to represent the outline of something. For example, to show the shape of the moon, we can draw a circle; to represent the surface of a table we can draw a rectangle; and so on. Virtually anything that can be perceived visually can be represented by a combination of points, lines, and shapes: e.g., in drawings of scenery, a cloud is represented as a shape, a horizon as a line.

Other visual signifiers include *value*, *color,* and *texture*. Value refers to the darkness or lightness of a line or shape. It plays an important role in portraying dark and light contrasts. Color conveys mood, feeling, and atmosphere in a visual text such as a painting. This is why we speak of 'warm,' 'soft,' 'cold,' or 'harsh' colors. Color, as will be discussed below, has culture-specific meanings: e.g., in American culture *yellow* connotes cowardice, while in China it connotes royalty. Texture refers to the phenomenon

Figure 2 Using lines with arrowheads to represent movement and direction.

that certain visual forms (lines, shapes, etc.) evoke tactile and other sensory modalities. Wavy lines, for example, tend to produce a much more pleasant sensation in a viewer than do angular ones. By increasing the number of edges on angular lines, the unpleasant sensation tends to increase proportionately. This is strong evidence that visual representation is intermodal, eliciting other sensory modalities in tandem. The term that is used to characterize this phenomenon is *synesthesia*. It is defined as the phenomenon in which the stimulation of one sense elicits a perception that ordinarily would be elicited had another sense been stimulated, as when a loud noise registers as a blinding light, or vice versa.

Digital Visual Signs

Today, elemental visual signifiers have found a new medium of representation – the digital one (Horn, 1998; Darley, 2000). Digital visual signs, such as the icon that designates a tiny picture on a computer screen, are proliferating. Each icon represents a command. The system of icons, pointer, and mouse is known as a graphical user interface (GUI), a system that provides a user-friendly way of interacting with a computer. Users can usually tell by the icons how to get the computer to do what they want. Without a GUI, the computer screen is black, and the only way to tell the computer what to do is to type in commands. There is little doubt that GUIs contributed to the rise of the personal computer in the mid-1980s, starting in 1984 when the Apple Computer Company introduced the Macintosh, the first personal computer to include a GUI. Because they make computers easy to use, GUIs quickly became standard throughout the computer industry. Today, most users encounter only GUI-based programs and never have to type in commands to control their computers.

Another common digital visual sign is the *emoticon* (literally an *icon* that conveys an *emotion* visually). Emoticons are strings of text characters that, when viewed sideways, form a face expressing a particular emotion. Common emoticons include the smiley :-) or :) (meaning 'I'm smiling at the joke here'), the winkey ;-) (meaning 'I'm winking and grinning at the joke here'), :-(('I'm sad about this'), :–7 ('I'm speaking with tongue in cheek'), :D or :-D (big smile; 'I'm overjoyed'), and :-O (either a yawn of boredom or a mouth open in amazement). In an e-mail message or newsgroup article, a letter, word, or phrase that is encased in angle brackets, indicating the attitude the writer takes toward what he or she has written, is called an *emotag*. Often emotags have opening and closing tags, similar to HTML tags, that enclose a phrase or one or more sentences. For example: <joke>*You didn't think there would really be a joke here, did you?*</joke>. Some emotags are used as single tags, such as <grin>.

Color Signifiers

As a signifier in visual representations color has become a target of much study, within both semiotics and linguistics (e.g., Hatcher, 1974; Hilbert, 1987; Davidoff, 1991; Hall, 1992; Hardin and Maffi, 1997; MacLaury, 1997; Tufte, 1997). At a perceptual (concrete) level, we interpret colors as gradations of hue on the light spectrum. Hue is the property that leads us to give a color its name – for example, *red*, *orange*, *yellow*, *green*, *blue*, or *violet*. But the naming process is hardly free of cultural factors. The actual color terms we use in English predispose us to see 'differential categories' of hue. Experts estimate that we can distinguish perhaps as many as 10 million hues. Obviously, then, our limited number of color terms is far too inexact to describe accurately all the hues we are potentially capable of perceiving. The restrictions imposed on color perception by color vocabularies are the reasons why people often have difficulties trying to describe or match a certain color.

In a real sense, color is what the color terms in a language say it is. Consider what happens by putting a finger at any point on the spectrum. Only a negligible difference in the hues immediately adjacent to the finger at either side would be perceived by a viewer. Depending on where one puts it, however, perception of the difference will vary. This is because we have become accustomed to 'seeing' the spectrum in terms of the color terms of the language we speak. But there

Figure 3 Differential classifications of the color spectrum.

is nothing inherently 'natural' about any color organizational scheme; it is a reflex of linguistic vocabulary, not of Nature. Speakers of Shona, an indigenous African language, for instance, divide the spectrum up into *cipswuka, citema, cicena,* and *cipswuka* (again), and speakers of Bassa (Basa), a language of Liberia, segment it into just two categories, *hui* and *ziza*. The relative proportional widths of the gradations that these color categories represent vis-à-vis basic English categories can be shown graphically (see **Figure 3**).

So, when an English speaker refers to something as *blue,* a Shona speaker might refer to it as either *cipswuka* or *citema,* and a Bassa speaker as *hui*; referring to something as *yellow, orange,* or *red* in English would be translated in Bassa as *ziza*; and so on. In this case, 'reality' is exactly what different people 'say' that it is. But this does not mean that the use of a specific set of color terms blocks people from seeing reality as others do. The color categories one has acquired in cultural context in no way preclude the ability to perceive the color categories used in other cultures. This is, indeed, what a learner of another language ends up doing when he or she studies the new color system. The student must learn how to reclassify the content of the spectrum in terms of new lexical categories. Moreover, in all languages there exist signifying resources for referring to more specific hues on the spectrum if the situation should require it. In English the words *crimson, scarlet, vermilion,* for instance, make it possible to refer to gradations of *red*. But these are still felt by speakers to be subcategories of *red*, not distinct color categories on their own.

The linguists Berlin and Kay (1969) argued, moreover, that differences in color terms are only superficial matters that conceal general underlying principles of color perception. Using the judgments of the native speakers of 20 widely divergent languages, they came to the conclusion that there were 'focal points' in basic (single-term) color systems that clustered and evolved in certain predictable ways. They identified eleven focal points, which corresponded to the English words *red, pink, orange, yellow, brown, green, blue, purple, black, white,* and *gray*. Not all the languages they investigated had separate words for each of these colors, but there emerged a pattern that suggested to them the existence of a fixed way of perceiving color across cultures. If a language had two colors, then they were equivalents of English *black* and *white*. If it had three, then the third one corresponded to *red*. A four-term system had either *yellow* or *green*, while a five-term system had both of these. A six-term system included *blue*; a seven-term system had *brown*. Finally, terms for *purple, pink, orange,* and *gray* were found to occur in any combination in languages that had the previous focal colors. Berlin and Kay found that languages with, say, a four-term system consisting of *black, white, red*, and *brown* did not exist. Berlin and Kay called this the *universal color system*.

The intriguing implications of Berlin and Kay's research were pursued vigorously in the 1970s by many linguists and psychologists. Eleanor Rosch (e.g., 1975), for instance, demonstrated that the Dani people of West Irian, who have a two-color system similar to the Bassa system described above, were able to discriminate easily eight focal colors. Using a recognition-memory experiment, Rosch found that the Dani recognized focal colors better than non-focal ones. She also found that they learned new colors more easily when the color names were paired with focal colors. Such findings suggested to Rosch that languages provided a guide to the interpretation of color, but they do not affect its perception in any way.

But many problems remain to this day with the conclusions reached by these color researchers. For one thing, the fact that the eleven focal colors posited by Berlin and Kay corresponded to the color terms of their own language (English) is suspicious. Could the researchers have been predisposed by their own language to gloss all other terms according to the English categories? Many of the terms Berlin and Kay listed, some critics have also pointed out, turn out to be borrowings (color terms taken and/or adapted from other languages), which would greatly undermine their theory. The focal points of Berlin and Kay's theory would seem to be no more than the points on the color spectrum categorized by the language to which they had become accustomed.

Semiotically speaking, color terms are verbal signifiers that predispose people to attend primarily to the hues they encode. This is a practical strategy; otherwise, millions of terms would need to be invented to classify the spectrum accurately. But the semiotic story of color does not stop there. Throughout the world colors are used for representational purposes. The archeological record strongly suggests,

Figure 4 A three-dimensional figure represented on a two-dimensional surface.

in fact, that sensory and emotional meanings attached to colors may even have been the source for the color terms themselves (Wescott, 1980). In Hittite, for instance, words for colors initially designated plant and tree names such as *poplar*, *elm*, *cherry*, *oak*, etc.; in Hebrew, the name of the first man, *Adam*, meant 'red' and 'alive,' and still today, in many languages, *red* signifies 'living' and 'beautiful.' In all societies, colors play a critical function in the realm of symbolism. The Navajo of North America, for instance, allocate to colors a hierarchy of symbolic importance – blue is 'good' and red 'bad'; nation societies perceive great significance in the colors of flags and national emblems; and the list could go on and on.

Visual Texts

A text is anything that has been put together with signs to represent something. Lines and shapes, for example, can also be combined to create three-dimensional figures, which are visual texts that create an illusion of depth in the viewer. In the visual text of Figure 4 there are 12 lines. The way they are put together, however, makes us perceive the text as a three-dimensional box (see Figure 4).

Although the figure has been drawn on a two-dimensional surface, we cannot help but perceive it as a three-dimensional box. The reason for this is that, as a visual text, it has been drawn with the technique of 'perspective drawing.' This deceives us, in effect, to view objects as the human eye perceives them. The flat surface of any drawn figure is known as the *picture plane*; the horizon line is called the horizontal *eye-level line* that divides the scene in the distance; and the *vanishing point* is located on the horizon line where parallel lines in the scene appear to converge. This makes certain parts of the figure appear to be closer than others (see Figure 5).

Figure 5 A figure drawn in perspective.

Perspective drawing is, in a phrase, the technique of creating an illusion of depth or length in two-dimensional surface drawings. As a historical footnote, it should be noted that the craft of perspective drawing dates back to the Renaissance, after the Italian artist Filippo Brunelleschi (1377–1446) developed the technique in Western painting.

There are many and varied types of visual texts, from paintings and drawings to maps, blueprints, comics, and the like, that have become targets of specialized areas of semiotics. Some of these, such as comic books, involve the use of both verbal and visual techniques, producing very effective texts (*see* **Semiotics of Architecture**; **Cartography: Semiotics**; **Comics: Semiotic Approaches**; **Photography: Semiotics**; **Pictography: Semiotic Approaches**).

Visual texts have an effect on perception, and can even mislead it. As a concrete example, consider the classic illusion in which the line AB appears to be longer than line CD (see Figure 6).

In actual fact the lines are equal in length, but the orientation of the arrowheads fools the eye into seeing AB as longer than CD. In some areas of the world, however, psychologists have found that people see the lines as equal in length. The factor behind this illusion is thus cultural, not biological – visual perception is intrinsically intertwined with representational practices. Psychologists have found that people living in cultures that have never been exposed to illustrated magazines are unable to recognize the photographs in the magazines as visual representations of human beings (Deregowski, 1972; Dunning, 1991). They tend to perceive them, rather, as smudges on the paper. Such erroneous interpretation of the photographs is not due to defects of intelligence or eyesight; on the contrary, the individuals are clear-sighted and highly intelligent. Their primary assumptions are different, because they have acquired a different system of visual representation that blocks them from perceiving the photographs in the same manner that those accustomed to viewing magazines perceive them.

Figure 6 Classic optical illusion.

Two types of visual texts that have been targets of great interest within visual semiotics are *diagrams* and *charts*. A diagram is a schematic drawing using basic visual signifiers (points, lines, shapes, etc.) designed to 'explain' visually how something works or to clarify the relationship between the parts of a whole. A chart is a diagram that is designed to contain and display information of various kinds. Diagrams are cognitively powerful visual texts that are indispensable in science and, typically, are the sum and substance of theory-making. The diagram of the atom as a miniature solar system with a nucleus and orbiting particles is, *ipso facto*, a theory of the atom, allowing us to envision it in a particular way.

The common use of diagrams and charts throughout the world suggests that sight is a dominant modality in conception and knowledge-making. The science of geometry is an exemplar of this point. Geometry is about 'ideal visual forms' such as triangles, circles, and squares. Amazingly, such forms have allowed us to draw inferences about reality and about ourselves. Ancient Greek geometry provided, in fact, the basic ideas that came to characterize the modern system of scientific investigation. Geometric diagrams, and theorems about them, have applications to the real world. In the history of science, this kind of 'diagrammatic cognition' has produced truly remarkable results. This is because, as the ancient Greek geometers emphasized, it permits representations of various aspects of physical reality which, in turn, allow for an intellectual experimentation with that very reality through the use of symbolic reasoning (e.g., the many scenarios suggested by the Pythagorean Theorem). The results of this experimentation can then be redirected to the real world to see what they yield. Symbolic reasoning in such areas of human thought carries the burden over intuition.

Writing

Although now considered a separate field of its own, within both semiotics and linguistics, writing is also included under the visual semiotic rubric. Writing has always been perceived as having a mystical function, not just a purely representational one. The ancient Egyptians called their writing system *hieroglyphic* because they used it to record hymns and prayers, to register the names and titles of individuals and deities, and to record various community activities – *hieroglyphic* derives from Greek *hieros* 'holy' and *glyphein* 'to carve' (Goldwasser, 1995). In their origins most scripts were deemed to have sacred or mystical function – for example, the Cretans attributed the origin of writing to Zeus, the Sumerians to Nabu, the Egyptians to Toth, the Greeks to Hermes, and so on.

The earliest form of writing was *pictographic*. This consisted of drawing pictures to represent objects. For example, a circle was used typically to represent the sun and a wavy line to represent a river. So intuitive is pictography that it comes as little surprise to find that it has not disappeared from even alphabet-based cultures. The figures designating *male* and *female* on washroom doors and the *no-smoking* signs found in public buildings, to mention but two common examples, are modern-day pictographs.

One of the first civilizations to institutionalize pictographic writing as a means of recording ideas, keeping track of business transactions, and transmitting knowledge was the ancient Chinese one. According to some archeological estimates, Chinese pictography may date as far back as the 15th century B.C.E. Another fully developed ancient pictographic system was the Sumerian-Babylonian one that was developed nearly five thousand years ago. The Sumerians recorded their pictographic representations on clay tablets with wedge-shaped forms, hence the name *cuneiform*. Cuneiform writing was a very expensive and impracticable means of writing. For this reason it was developed, learned, and used primarily by rulers and clerics. In Egypt, hieroglyphic writing emerged around 2700 to 2500 B.C.E. The Egyptians used papyrus (a type of early paper made from reeds) to record their writings, making it more practicable for many more classes of people.

More abstract forms of pictographic signs are called *ideographs*. These may bear some resemblance to their referents, but require acquired knowledge of the relation between picture and referent on the part of the user. International symbols for such things as public telephones, washrooms, etc., are all ideographic. More abstract ideographs are known as *logographs*. A logographic system combines various pictographs and/or ideographs for the purpose of indicating nonpicturable ideas. For example, the Chinese pictographs for *sun* and *tree* are combined to represent the Chinese spoken word for *east*. The first *syllabaries* – systems of signs standing for syllables – developed from such amalgamated systems. Syllabaries are still used in some cultures. Japanese, for example, is still written with two complete

syllabaries – the *hiragana* and the *katakana* – devised to supplement the characters originally taken over from Chinese.

To facilitate the speed of writing, the Sumerians and the Egyptians eventually streamlined their pictographs and transformed them into symbols for the actual sounds of speech. Called *phonographic* writing, it consisted of signs standing for parts of words, such as syllables or individual sounds. A complete phonographic system for representing single sounds is called *alphabetic*. The first alphabetic system emerged in the Middle East around 1000 B.C., and was then transported by the Phoenicians (a people from a territory on the eastern coast of the Mediterranean, located largely in modern-day Lebanon) to Greece. It contained signs for consonant sounds only. When it reached Greece, signs for vowel sounds were added to it, making the Greek system the first full-fledged alphabetic one.

The Greeks also started the practice of naming each alphabet sign by such words as *alpha, beta, gamma*, etc., which were imitations of Phoenician words: *aleph* 'ox,' *beth* 'house,' *gimel* 'camel,' etc. Incidentally, the idea of an 'alphabetic order' of letters from **A** to **Z** emerged because the letters were used to count the numbers in order – **A** stood for 1, **B** for 2, **C** for 3, and so on. The earliest record of alphabetic order is Psalm thirty-seven where verses follow the Hebraic sequence.

Alphabetic writing has become the norm in many cultures. But in every alphabetic sign, there is a pictographic history and prehistory similar to the one described above for the letter **A.** The pictographic content of our letters goes unnoticed because our eyes are no longer trained to extract pictorial meaning from them.

Conclusion

There is no culture without visual representational traditions and customs. These bear witness to the fact that visual signs are perceived to be just as crucial to human understanding, if not more so, than words. As mentioned, the study of visual signs embraces a number of subfields, from painting to photography, within general semiotics. However, in its basic outline, the goal of visual semiotics is to study the elements of visual representation and how these help human beings understand reality.

Learning Burden

Knowing a word well involves knowing several aspects covering the form, meaning, and use of the word. The difficulty these aspects have for any particular word depends on how closely the aspects relate to knowledge the learners already have. This knowledge can come from the learners' first language or other languages they know, and it can come from the knowledge they already have of the second language. For example, if the learners' first language uses the same written script as the second language, then this will make the learning burden of the written form of the second language much lighter. If the written form of the second language is very regular with one letter always representing the same sound and vice versa, then the learning burden of the written form will be even lighter. Similarly, if the two languages share a lot of cognate vocabulary, some of the learning burden will be lighter. Spanish learners learning the academic vocabulary of English find that these words have a light learning burden because most have very similar forms and meanings in English, for example *acquisition* and *evaluation*. Finnish learners of English are faced with a more difficult task.

Teachers can try to lighten the learning burden of a word by explicitly relating it to known items that are similar in the first or second language, by showing the patterns or rules that the word fits into, and by preteaching items and features that will make the new word easier to learn. Before teaching a word, it is worth doing a quick analysis of the learning burden of the word to work out what aspects of the word the teaching needs to focus on.

Word Form

Words that are difficult to pronounce are usually difficult to learn (Rodgers, 1969; Ellis and Beaton, 1993). Words that are easy to pronounce can more easily be held in working memory and thus have a greater chance of entering long-term memory. Thus, the words introduced early in an English course should be easy for learners to pronounce. Substantial listening practice and a small amount of guided pronunciation practice can make it easier for words with unfamiliar sounds to be learned.

Although English spelling is notorious for its irregularities, there are numerous patterns and rules that can help learning. First language research on reading has shown that developing phonemic awareness (the idea that words are made up of separable sounds) can have very positive effects on learning to read English (Ehri *et al.*, 2001). Similarly, giving some attention to phonics (sound-spelling relationships) can also help with learning to read and write (Stahl *et al.*, 1998). A very large proportion of English words come from French, Latin, or Greek and thus make use of prefixes, suffixes, and stems that can occur in many different words. Learning can be helped if the most common affixes and their meanings are learned, and often a simple explanation of a word's etymology (e.g., the word *rank* has the same stem as the word *arrange*) can help learning. Irregular affixation can increase the learning burden. Laufer's (1997) study of

Learning Burden

Knowing a word well involves knowing several aspects covering the form, meaning, and use of the word. The difficulty these aspects have for any particular word depends on how closely the aspects relate to knowledge the learners already have. This knowledge can come from the learners' first language or other languages they know, and it can come from the knowledge they already have of the second language. For example, if the learners' first language uses the same written script as the second language, then this will make the learning burden of the written form of the second language much lighter. If the written form of the second language is very regular with one letter always representing the same sound and vice versa, then the learning burden of the written form will be even lighter. Similarly, if the two languages share a lot of cognate vocabulary, some of the learning burden will be lighter. Spanish learners learning the academic vocabulary of English find that these words have a light learning burden because most have very similar forms and meanings in English, for example *acquisition* and *evaluation*. Finnish learners of English are faced with a more difficult task.

Teachers can try to lighten the learning burden of a word by explicitly relating it to known items that are similar in the first or second language, by showing the patterns or rules that the word fits into, and by preteaching items and features that will make the new word easier to learn. Before teaching a word, it is worth doing a quick analysis of the learning burden of the word to work out what aspects of the word the teaching needs to focus on.

Word Form

Words that are difficult to pronounce are usually difficult to learn (Rodgers, 1969; Ellis and Beaton, 1993). Words that are easy to pronounce can more easily be held in working memory and thus have a greater chance of entering long-term memory. Thus, the words introduced early in an English course should be easy for learners to pronounce. Substantial listening practice and a small amount of guided pronunciation practice can make it easier for words with unfamiliar sounds to be learned.

Although English spelling is notorious for its irregularities, there are numerous patterns and rules that can help learning. First language research on reading has shown that developing phonemic awareness (the idea that words are made up of separable sounds) can have very positive effects on learning to read English (Ehri *et al.*, 2001). Similarly, giving some attention to phonics (sound-spelling relationships) can also help with learning to read and write (Stahl *et al.*, 1998). A very large proportion of English words come from French, Latin, or Greek and thus make use of prefixes, suffixes, and stems that can occur in many different words. Learning can be helped if the most common affixes and their meanings are learned, and often a simple explanation of a word's etymology (e.g., the word *rank* has the same stem as the word *arrange*) can help learning. Irregular affixation can increase the learning burden. Laufer's (1997) study of

synforms has shown that, when knowledge of a form is not firmly established, there can be considerable interference with words of roughly similar form.

Word Meaning

If an L2 word is a loan word or a cognate in L1, it is then very easy to relate the form of the word to its meaning. For example, approximately 70% of the 570 words in Coxhead's (2000) Academic Word List exist in Spanish in a similar form with a similar meaning. Only a very small number, approximately 10%, are false cognates in which the form is similar but the meaning is not. The reason for such a large overlap is that over half of English words came to English from French or Latin (Roberts, 1965). As a result, other languages derived from or with a lot of borrowing from Latin and related languages share a large amount of vocabulary. One important effect of this is that the analysis of words into parts, particularly giving attention to prefixes and suffixes, can greatly help the learning of these words. Remembering the meaning of a regularly affixed word such as *unpredictable* or *miscommunication* is helped by having an understanding of the parts that make it up. There are lists of the most frequent, regular, productive, and predictable affixes in English that learners of English as a second language can usefully learn (Bauer and Nation, 1993).

Some English words require considerable concept development by learners with particular first languages. The most striking of these may be words for family relationships and pronouns if English uses a system different from that in the first language. For example, in the Thai system for showing family relationships, relative age is very important and the term used to refer to an older sister is different from that used to refer to a younger sister. Similarly an aunt on your mother's side who is younger than your mother is referred to in a different way from one who is older than your mother. Learning such a system takes a lot of time and experience for a nonnative speaker.

Some areas of technical vocabulary may also present a heavy learning burden. Recent studies of technical vocabulary (Chung and Nation, 2003) have shown that a very large proportion of the running words in specialized texts are technical words. In highly technical subjects such as anatomy almost one in every three words is a technical word. In other areas, this may drop to one in five. From a learning-burden perspective, technical vocabulary can be divided into two types: technical words that have forms that are largely unique to the specialized area and words that also occur in nonspecialized areas, usually with the same or a related meaning. The first group includes words such as *thorax, sternum,* and *vertebrae* in anatomy and *pixel, ROM,* and *cpu* in computing. The second group includes words such as *by-pass, chest,* and *rib* in anatomy and *file, open,* and *save* in computing. Usually the completely new words such as those in the first group will have a heavier learning burden because both a new form and a new concept must be learned. Words in the second group can be made easier to learn by relating their nontechnical meaning to their technical meaning.

When learning most other words, the learner may find the L1 equivalent to be sufficient as a first step in developing an L2 concept for the word. If a word has a wide range of senses that do not correspond to the L1, then this can increase learning burden.

Word Use

If the grammar and collocations of a word are not similar to those in the first language or to known second language synonyms, then the learning burden is heavy and teachers may need to spend time on these aspects. Collocations are words that typically occur with other words. Some typical collocates of *sweet* in the British National Corpus are *smile, smell, flavour, dreams, tooth, boy, juice,* and *dreams*. If these do not parallel the first language, then they need to be learned. This is probably best done through extensive experience with the language. Such learning can also be helped by drawing attention to the concept underlying the range of uses of the word (*sweet* shows that something is pleasing and well liked) and by explicit attention to the collocates. It has been suggested that it is knowledge of collocational units that makes native speakers sound nativelike and that allows them to use the language fluently (Pawley and Syder, 1983). That is, native speakers can use the language well because they have stored units of language that are much larger than a word. Storing and accessing units such as *that's all very well for you to say* and *without further ado* allow a speaker to produce accurate language quickly.

Some words such as *faucet, kid, bugger,* and *explicate* have restrictions on their use. These restrictions include geographical restrictions (Americans use *faucet*; British use *tap*), register (*expedite* is very formal; *speed up* is more colloquial), currency (some words such as *forsooth* and *breeches* are no longer in use), age restrictions (*potty* and *choo-choo* are used by and with children), gender restrictions (*fabulous* tends to be used by women), and frequency (some words such as *diligent* and *capricious* are not commonly used). When learning and using these words, these restrictions need to be noted.

Idioms

Most groups of words (multiword units) in normal language are easy to comprehend if the words that make up the multiword unit are known. So, understanding *is the food good?* and *they are going to the city* is not usually problematical. Some multiword units, however, have a meaning that is very different from the meaning of their parts. Carefully applying the criteria of noncompositionality and nonfigurativeness, Grant and Bauer (2004) made an exhaustive search of idiom dictionaries, articles about idioms, language teaching texts, and television scripts to find all the English core idioms. The term 'core idiom' was used to distinguish it from the looser uses of 'idiom.' For example, *by and large* is a core idiom because the meaning of *by and large* cannot be related to the meaning of the individual words *by* and *large* – that is, it is noncompositional – and we cannot visualize some figurative use of *by and large* relating it to its meaning – that is, it is nonfigurative. On the other hand, *the worm turns* is not a core idiom. We can imagine or visualize a mild worm turning fiercely on an attacker (which conveys the meaning of the phrase), and so it is a figurative and thus not a core idiom.

Only 104 core idioms were found. Each of these items was then searched for in the British National Corpus (BNC) to find its frequency, various forms, literal uses, and collocations. The most frequent core idiom, *by and large*, occurred 487 times in the 100 000 000 token corpus. This frequency is not sufficient to get it into the most frequent 5000 words of English. Most of the core idioms occurred fewer than 50 times per 100 000 000 running words, and 18 of them did not occur at all in the BNC.

Core idioms are usefully distinguished from other types of multiword units because they require different interpretation and learning procedures. They have to be treated as unanalyzed wholes. Figuratives and collocations can be learned by analyzing their parts.

Fifty-nine of the 104 core idioms were not frozen; that is, they had variations in the BNC, some of them quite substantial. If frozenness was added to the criteria for a core idiom, there would only be 45 English core idioms.

A few core idioms such as *a piece of cake, beat it,* and *Uncle Sam* have literal equivalents; *a piece of cake* is most often literally 'a piece of cake' not 'something easy to do.' Forty-nine of the 104 had no literal equivalents, and a further 34 were very unlikely to have literal equivalents.

Core idioms are a small group of infrequent items. They do not deserve teaching time, but learners may benefit from some help in choosing and using an idiom dictionary.

Learning Conditions

Ease or difficulty of learning can be affected by the conditions under which the learning takes place. Crothers and Suppes (1967) found that when the learning burden of the words was heavy, it was more effective to learn small groups of words (around 20) rather than larger groups. In the early stages of language learning, the learning burden tends to be high because the learner is unlikely to be familiar with the systems and patterns of the new language. When the learning burden is low, it is much more effective to learn much larger groups of words.

Deliberate and Incidental Learning

Experiments involving deliberate learning show learning rates and long-term retention rates that far exceed those from incidental learning (Nation, 2001: 298–299). Similarly, in message-focused learning through speaking activities, vocabulary whose meaning is overtly negotiated is much more likely to be learned than that which is quietly guessed from context clues. There are several issues to consider here. First, incidental learning and deliberate learning should not been seen as competitors; they can be mutually reinforcing, and thus it is better to have both types of learning rather than just one. Second, it is not clear how to apply the label 'difficulty' properly to these two kinds of learning. The deliberate learning of vocabulary and negotiation of vocabulary involve more focused effort. Incidental learning, in the short term at least, is less effective but also involves much less focused effort. If difficulty is measured by results then deliberate learning is easier. If it is measured by the amount of focused effort, then incidental learning may be easier. One of the best studies of incidental vocabulary learning was carried out by Waring and Takaki (2003). They looked at incidental learning from reading one graded reader containing 25 target words. After the learners read the text, Waring and Takaki tested each target word in three different ways. The easiest test was a recognition test in which the learners saw a list of 42 words and had to indicate which ones occurred in the story they had just read. The average score was around 16 out of 25. A multiple-choice test required them to choose the most suitable meaning for each word from four choices. The average score was 10 out of 25. The most difficult test was a translation test that required the learners to translate a given word into their first language. The average score was around 4 out of 25. The translation test is the one closest to what the learners might need to do while they read, and the score was low. However, if the total learning

as revealed by the three tests is considered, it is clear that quite a lot of learning occurred that would be built on by further encounters with the words.

Involvement Load

Involvement load (Hulstijn and Laufer, 2001) is an attempt to measure the amount of mental processing that learners do when working on a vocabulary learning task. The three factors that Hulstijn and Laufer focused on are (1) need (Is the vocabulary needed to complete the task?), (2) search (Do the learners have to look for the word form or meaning or are they already provided?), and (3) evaluation (Do the learners have to decide if the word or meaning chosen is the most suitable one?). Hulstijn and Laufer rated each task they studied using the three factors, scoring the role of each factor as 0, 1, or 2. The involvement load of the task was the sum of the ratings for each of the three factors. Hulstijn and Laufer's studies showed that the greater the involvement load, the more likely a word was to be learned. This finding parallels those on generative use, that is, using a word in creative ways, which show that the more generatively a word is used, the more strongly it is learned (Joe, 1998). These studies relate increased mental effort to more effective learning.

Negotiation

What at first glance seems like a contradiction to this finding comes from studies involving negotiation of vocabulary. Negotiation occurs when learners try to work out the meaning of an item by discussing it with one another. Here is an example from Nation and Hamilton-Jenkins (2000).

> S12: bus driver? I don't think so
> S10: bus driver because it is . . .
> S9: if you don't have a licence how can you drive a bus, the police will catch me (The others agree)
> S11: I see so we need **registoration**
> S12: . . . so bus driver also need **reg** . . . **registration** because of competence so at first I think teacher, doctor, and lawyer is a very specific occupation so um it um at first they have to go to the university and polytech so they need require **registration** so ah in my opinion er I bus driver . . . if we want to be bus driver only we have ah licence and then we can ah get as a driver so I don't forget **registration** so I mistaked ah Japanese guess
> S10: maybe it is not **registration**, maybe it is not **registration**, I think maybe it is only bus driver licence . . .
> . . . maybe **registration** is just like a list where you can find some name like doctor.

Several studies have shown that learners who quietly observe negotiation taking place learn just as well as those who actively negotiate (Stahl and Clark, 1987; Ellis and Heimbach, 1997). Stahl and Clark deliberately designed this feature into their experiment. The learners were divided into three groups. One did the activity, which involved discussing things with one another. A second group observed the activity, but were told that they would be tested on what happened in the activity. The third group just observed with no expectation of being tested. All three groups were tested, and it was found that those who did not expect to be tested did not learn as well as those who did.

One problem with the vocabulary studies of such learning is that vocabulary knowledge was measured using only one test, so it was not possible to see how well each learner knew each word. However, putting this aside, the studies show that it may not be overt effort that determines learning but mental effort. Negotiation involves mental involvement. It also provides opportunities for generative use. Generative use occurs when a word is used in a way that is different from the ways in which it has been used or met before (Joe, 1998). This difference may be quite small (the word is used in the plural rather than the previously met singular form) or large (the word is used with new collocates). The bigger the difference (the greater the generativity), the stronger the learning resulting from the use is likely to be.

Strength of learning can be measured by testing each word in, preferably, three different ways with tests of varying degrees of sensitivity as in the Waring and Takaki experiment. Strength of knowledge is determined by adding together the scores for the three tests for each word.

When learners negotiate the meanings of items, they put the word into new contexts; that is, they use the word generatively. Several of these contexts may be metalinguistic contexts: *What does 'shed' mean? How do you spell 'tiger'?* The power of negotiation may be that it causes the learners to give focused deliberate attention to an item and that it results in generative use of the item. Negotiation thus sets up conditions that encourage learning.

Interference

There are now several studies that show that learning related items together makes learning more difficult (Higa, 1965; Tinkham, 1997; Waring, 1997). If near-synonyms (*bring* and *take*), opposites (*fat* and *thin*), free associates (*knife* and *fork*), or members of a lexical set such as articles of clothing or types of fruit are learned together, then learning is 50–100% more difficult (Nation, 2000). That is, learning the days of the week in the same lesson is much more

It is red
black
blue
green
white
yellow

Figure 1 Sample substitution frame.

difficult than learning one of the days of the week and six other unrelated words. The difficulty is even greater if words have some formal similarity to each other, so *Tuesday* and *Thursday,* for example, are especially likely to interfere. The difficulty occurs because crossassociations are made between the word forms and their meanings. So, for example, the word *white* may be associated with the meaning 'black,' and *black* may be associated with the meaning 'white.'

This difficulty can manifest itself in several ways. If learners have worked out some kind of mnemonic or luck is on their side, then the wanted associations may be made. Another possibility, as already described, is that the items are crossassociated. A more common possibility is that the learner realizes that *black* and *white* are two of the colors but is uncertain which is which. Most textbook writers are clearly not aware of this source of difficulty. Tinkham (1997) found that words that were related such as the words in a story, for example, *frog, green, slimy, pond,* and *splash*, were easier to learn together than unrelated words or members of a lexical set. If we attempt to generalize about the interfering and facilitating relationships, we can see that items that would be listed one under the other in a substitution or paradigmatic relationship (Figure 1) are likely to interfering.

Items that are in a syntagmatic relationship *the green slimy frog jumped into the pond with a splash* are likely to be easier to learn together than unrelated items or items in a paradigmatic relationship. This has implications for lesson planning. If a course book writer chooses a topic such as colors, clothing, or at the fruit shop, interference is likely to result. If, however, the lesson is organized around a story, there is less likelihood of interfering relationships occurring. Interference occurs when most or all of the items in a set are unknown. Once most or all of the items are known, there is some value in bringing them together to see what the distinctions between them are. If, however, the learning of the items is not already reasonably well established, then interference will occur.

The way words are grouped in lessons can have a major effect on learning difficulty. Once interference has occurred, then some mnemonic trick is needed to establish the correct associations.

Massed versus Spaced Learning

The same words can be studied intensively for a period of time (massed learning), or they can be repeatedly studied for briefer periods of time at increasingly spaced intervals (spaced or distributed learning). That is, a learner could spend an hour studying a group of 30 or so words, or the learner could spend 10 minutes studying them now, in an hour's time spend another 10 minutes, and then in 4 or 5 hours time another 10 minutes and then continue in this way the next day and so on. In total, the spaced learning could total 1 hour. Experiments comparing massed and spaced learning show much better results for spaced learning (Bloom and Shuell, 1981; Dempster, 1987; Baddeley, 1990). The repetitions should be spaced further and further apart. The principle behind this is that the older a piece of learning is, the slower the forgetting. This means that soon after something is first learned, forgetting occurs quite quickly. There needs to be another repetition before too much is forgotten. After the next repetition, the learning is now older and so the forgetting does not occur as quickly as it did the first time. It will thus take a little longer for the forgetting to reach the point where another repetition is needed. Pimsleur (1967) proposed a formula, which should not be taken too seriously but which provides a very useful and easy to remember guide for spacing repetitions: The time to the next repetition should be the square of the time between the two previous repetitions. So, if a word was studied and then looked at again 5 minutes later, the next repetition should be 5×5 minutes later (25 minutes later), the next 25×25 minutes later (10.5 hours later), the next 10.5×10.5 hours later (approximately 4 days later), and so on.

First Language Definitions

Learning vocabulary is easier if the meanings of words are conveyed in short, clear ways. The more detailed and complicated a definition, the more difficult it is for both native and nonnative speakers to understand. The main reason is that there tends to be too much information for a learner to focus on and the learner chooses just one part to latch on to. This usually misrepresents the meaning of the word. One of the clearest and simplest ways of providing a meaning for a word is to give a first language translation. This has several advantages: (1) the translation is usually short and clear, (2) it is usually in the form of a synonym rather than a definition (definitions are more difficult to understand because of their complex grammatical structure), (3) the new word is related to something the learners already know well, and (4) the meaning is presented in totally familiar language.

There is some experimental evidence that translations are an effective way of conveying meaning (Lado *et al.*, 1967; Mishima, 1967; Laufer and Shmueli, 1997). If other ways of conveying meaning, such as pictures, objects, demonstrations, and second language synonyms can meet these same criteria, they are also likely to be very effective. Often, however, they do not.

Many of the factors involved in the learning burden and difficulty can be manipulated to some degree by teachers and course designers. Aspects of the learning burden can be lightened by pointing out analogies with known items, by drawing attention to patterns or rules, and by directing deliberate attention to the particular aspect. Learning conditions are even more manipulable. George (1962) pointed out that teaching can have three effects: a positive effect in which teaching results in learning that takes the learners forward in their knowledge, a neutral effect in which nothing is learned, and a negative effect (the result of 'unteaching') in which the teaching results in learning that confuses or upsets previous learning. Good teachers can also be good 'unteachers.' An awareness of factors such as involvement load, negotiation, generative use, interference, and spaced repetition can reduce 'unteaching' and make the time spent on teaching and learning more productive and enjoyable.

Vocal Production in Birds

G J L Beckers, Leiden University, Leiden, The Netherlands and Max Planck Research Insitute for Ornithology, Seewiesen, Germany

© 2006 Elsevier Ltd. All rights reserved.

Bird vocalizations are widely noted for their extreme diversity in acoustic structure and sometimes high degree of complexity. Understanding the mechanistic basis of vocal performance in birds has been a long-standing effort. This is largely because of intrinsic scientific interest, but also, more recently, due to the growing importance of birdsong as an animal model system for the development and neurobiology of human speech. In this article, I review some highlights of current knowledge on the peripheral mechanisms underlying vocal production in birds and point out notable parallels and differences with speech production in humans.

Principles

The biophysical principles of vocal production in birds are similar to those involved in voiced speech of humans. Air flow, induced by the action of respiratory muscles, is modulated by vibrating structures in a voice organ, a process that causes acoustic pressure waves. These waves propagate through the air spaces of the vocal tract and eventually radiate into the outside environment. The exact characteristics of the sound that is produced depend on the vibration properties of vocal source, the acoustic resonances of the vocal tract, and the acoustic radiance function of the structure from which the sound eventually is emitted, e.g., the beak or 'vocal sacs.' To a first approximation, vocal production in birds can be explained, like human speech, by considering the properties of the vocal source and vocal tract independently, even though they function as one system and interactions between these two components may sometimes occur.

Vocal Source

Voice Organ

Vocal source vibrations in birds are generated by a unique voice organ, the 'syrinx,' which is an evolutionary innovation not found in any other group of animal. Birds also possess a larynx, which is the voice organ in mammals, reptiles, and anurans, but the larynx has not been found to be involved as a sound source in bird vocalization. The sole function of the syrinx is sound generation, and from a vocal production point of view it may therefore be less constrained in its mechanical design than the larynx, which also has functions related to respiration and feeding. For this reason perhaps, many birds appear to be much better vocal performers – at least from a production point of view – than any laryngeal vocalizer, including humans.

The syrinx consists of a modification of the airway at the junction of the trachea and bronchi and is situated in an air sac deep inside the thoracic cavity. In general, it comprises a cartilaginous or bony framework containing vibratory structures, either membranes or labia, and muscles that control the geometric configuration of the framework. The specific morphology of the syrinx, however, may differ considerably between bird taxa, even in basic design.

The most complex syrinx is found in the most virtuous singers among birds: the songbirds (suborder Oscines or Passeres, comprising approximately 40% of all bird species). The songbird syrinx is special because it has two sound sources, a voice at the cranial end of each bronchus, which can be controlled independently by highly specialized musculature (**Figure 1**).

The bipartite nature songbird of the syrinx is exploited in various ways across taxa to enhance vocal performance in spectacular ways. For example, in many songbirds, each syringeal voice specializes in its own vocal register – the left voice usually covers a

Vocal Production in Birds

Bird vocalizations are widely noted for their extreme diversity in acoustic structure and sometimes high degree of complexity. Understanding the mechanistic basis of vocal performance in birds has been a long-standing effort. This is largely because of intrinsic scientific interest, but also, more recently, due to the growing importance of birdsong as an animal model system for the development and neurobiology of human speech. In this article, I review some highlights of current knowledge on the peripheral mechanisms underlying vocal production in birds and point out notable parallels and differences with speech production in humans.

Principles

The biophysical principles of vocal production in birds are similar to those involved in voiced speech of humans. Air flow, induced by the action of respiratory muscles, is modulated by vibrating structures in a voice organ, a process that causes acoustic pressure waves. These waves propagate through the air spaces of the vocal tract and eventually radiate into the outside environment. The exact characteristics of the sound that is produced depend on the vibration properties of vocal source, the acoustic resonances of the vocal tract, and the acoustic radiance function of the structure from which the sound eventually is emitted, e.g., the beak or 'vocal sacs.' To a first approximation, vocal production in birds can be explained, like human speech, by considering the properties of the vocal source and vocal tract independently, even though they function as one system and interactions between these two components may sometimes occur.

Vocal Source

Voice Organ

Vocal source vibrations in birds are generated by a unique voice organ, the 'syrinx,' which is an evolutionary innovation not found in any other group of animal. Birds also possess a larynx, which is the voice organ in mammals, reptiles, and anurans, but the larynx has not been found to be involved as a sound source in bird vocalization. The sole function of the syrinx is sound generation, and from a vocal production point of view it may therefore be less constrained in its mechanical design than the larynx, which also has functions related to respiration and feeding. For this reason perhaps, many birds appear to be much better vocal performers – at least from a production point of view – than any laryngeal vocalizer, including humans.

The syrinx consists of a modification of the airway at the junction of the trachea and bronchi and is situated in an air sac deep inside the thoracic cavity. In general, it comprises a cartilaginous or bony framework containing vibratory structures, either membranes or labia, and muscles that control the geometric configuration of the framework. The specific morphology of the syrinx, however, may differ considerably between bird taxa, even in basic design.

The most complex syrinx is found in the most virtuous singers among birds: the songbirds (suborder Oscines or Passeres, comprising approximately 40% of all bird species). The songbird syrinx is special because it has two sound sources, a voice at the cranial end of each bronchus, which can be controlled independently by highly specialized musculature (Figure 1).

The bipartite nature songbird of the syrinx is exploited in various ways across taxa to enhance vocal performance in spectacular ways. For example, in many songbirds, each syringeal voice specializes in its own vocal register – the left voice usually covers a

lower range than the right voice. Songbirds such as the Northern cardinal, *Cardinalis cardinalis*, use this system to produce seemingly continuous notes modulated over extreme frequency ranges, by starting phonation on one side of the syrinx and quickly switching to the other side in the middle of the note. Other birds such as the brown thrasher, *Toxostoma, rufum*, use the two-voice system to simultaneously produce unrelated sounds and thus sing a duet in solo. A totally different approach to achieve vocal virtuosity using a bipartite syrinx is taken by Waterslager canaries, *Serinus canaria*, which can sustain high syllable-repetition rates, sometimes exceeding 30/s, for long periods of time, sometimes exceeding 30s, without taking a pause for a normal inspiration. This is achieved by using the left syrinx side for phonation while the right side is used to take so-called mini-breaths in between each syllable. Such a system allows the left side to be kept in phonatory position while the right side is able to maintain respiratory air supply for phonation, a specialisation that increases the duration of the period in which fast syllable repetition can be sustained.

Less complex or even relatively simple syrinxes are found in nonsongbird taxa, which, overall, comprise less virtuous vocalizers. However, attempts to find a clear and systematic relationship between syringeal complexity and phonetic complexity in birds have failed thus far.

Voice Mechanism

The actual mechanism by which sound is generated in the syrinx has been a long-debated topic. Normally, voice production in tetrapods involves a pneumatic valve-type sound generator, such as the laryngeal voice in mammals, in which vibrating vocal folds periodically close and open the airway lumen, causing a train of air pulse releases in the vocal tract. Such a system characteristically produces a sound with a fundamental frequency and a series of harmonic overtones. However, birds often produce pure-tone song, which lacks the characteristic stack of harmonic overtones of a valve-type source. For this reason, a variety of alternatives to a valve-type sound generator have been proposed for pure-tone bird vocalization, the most notable of which is an aerodynamic whistle mechanism. However, recently it has been shown that pure-tone song in doves (nonsongbirds) is generated by the syrinx as a sound with harmonic overtones, which is subsequently filtered by the vocal tract to a pure tone before the sound is emitted. Moreover, direct video observation of the syrinx in phonating birds shows that vibrating membranes or labia form a slot in the airway lumen. Pure-tone phonation, as well as other types of phonation observed in birds, can therefore in principle be explained on the basis of a normal valve-like source mechanism in the syrinx, similar to laryngeal voice mechanisms in humans. Nevertheless, given the extreme diversity in syringeal structure across species, it remains possible that fundamentally different mechanisms of syringeal sound generation exist in birds.

Modulation of Voice

Source phonation in birds is usually modulated in time to generate complex spectrotemporal vocal patterns. There are two fundamentally different ways in which this is achieved.

First, coordinated neuromuscular control of the respiratory and syringeal systems can directly modulate biophysical characteristics of the voice system, so that spectral patterns and overall amplitude of the sound that is produced at the syrinx change over time. The fundamental frequency of phonation in songbirds, for example, changes by the action of ventral syringeal muscles, which presumably regulate the tension of the vibrating labia, whereas in dove coo phonation, frequency is modulated by changes in air sac pressure achieved by respiratory muscles. Likewise, vocal amplitude is known to be controlled by a variety of direct neuromuscular mechanisms in birds.

A second and relatively little known mechanism of modulation arises spontaneously from intrinsic properties of the vocal production system. The primary sound generators in birds, vibrating labia or membranes, are in fact **nonlinear** oscillators, and it has been observed in diverse scientific fields that coupled nonlinear oscillators in general can also exhibit complex dynamics **without** any external, complex control (nonlinear dynamics or 'chaos theory'). The key point about nonlinear dynamics in vocalization is that a relatively simple system, such as two coupled vibrating membranes, can give rise to a series of different states of oscillatory behavior, which include amplitude and frequency modulations. Most likely, at least the extremely rapid periodic modulations found in bird vocalizations, which sometimes exceed 500 Hz and are unlikely to be under direct muscle control, originate from such intrinsic dynamics, as do discontinuous modulations such as the often observed frequency jumps ('voice breaking').

Most bird vocalizations that are described as 'noisy' are likely also due to nonlinear dynamics and may be produced by a chaotic oscillatory state of the syrinx. It is interesting to note that this is in contrast with noisy sound sources in human speech, such as whispered consonants (e.g., English *h*), which do not originate from vocal fold oscillations but from air turbulence in the vocal tract, a process that indeed is truly random or noisy. Chaos, however, is completely deterministic and only superficially resembles noise in spectrographic representation. Nevertheless, some bird vocalizations may actually originate from a true noise source, at least as judged by the human ear, for example, hissing in swans.

Vocal Tract

The sound that is generated by the syrinx depends not only on its oscillatory dynamics, but also on the specific acoustic impedance at the syrinx. That is, source vibrations at some frequencies produce sound more easily than those at other frequencies, a pattern that is determined by the geometry of surrounding vocal tract air cavities such as the bronchi and trachea. Moreover, as sound propagates through the vocal tract it may undergo further filtering through changes in tract diameter, which cause acoustic impedance changes. Thus, the avian sound production system should be viewed as a source–filter system, in which the syrinx provides the necessary source vibrations and the filter determines the amplitudes of the sound frequencies produced.

Although acoustic filtering of syringeal source vibrations is physically inevitable, it has been a matter of long-term debate how important vocal tract filtering actually is in shaping specific time–frequency patterns in bird vocalization and which mechanisms are used to shape vocalizations. Three models of vocal tract filtering have been suggested in the literature, each of which is likely to occur in birds.

In the simplest model, the vocal tract could act as a static broadband filter that leaves the relative amplitudes of all frequencies produced by the syrinx more or less unaffected. In an alternate version of this model, the vocal tract could act as a static bandpass filter with a bandwidth that is smaller than the frequency range in which the syrinx produces sound (**Figure 2**, 'Static filter'). The latter mechanism approximates the situation in dove coos, where harmonic overtones produced by the syrinx are filtered out so that only the fundamental frequency remains. Such a mechanism can be used only when relevant sound features, in the case of doves the fundamental frequency, are modulated within the existing static vocal tract pass-band.

In a second model, the frequency range over which the syrinx modulates relevant sound features is much larger than the bandwidth of the vocal-tract filter, in which case the vocal tract must dynamically adjust resonance frequencies in order to track the changes in phonation frequency (see **Figure 2** 'Dynamic filter tracking source'). This mechanism is more complex because the dynamic tracking requires close motor coordination between the syringeal source and vocal tract articulators. However, the vocal tract does not create complex phonetic patterns independently of the source. As an example of this mechanism, it has been suggested that the beak gape changes that often occur during bird vocalizations adjust the frequencies of vocal tract resonance peaks so that they follow a particular harmonic frequency produced by the syrinx. Recent research has shown that beak gape changes do indeed modulate vocal tract filtering characteristics, but not through the shifting of resonance peaks. This notwithstanding, the argument may hold for other vocal tract articulators.

Finally, analogous to human speech production, a dynamic vocal tract filter can create its own complex time–frequency patterns, independently of source modulations generated by the syrinx (**Figure 2**, 'Dynamic filter with independent modulation'). This makes sense only if the syringeal source produces a wide-band sound, such as a harmonic stack. An example of such a mechanism occurs in parrots, whose tongue movements cause significant and complex changes in four vocal tract resonances or 'formants.' Analysis of parrot mimic speech and natural

Figure 2 Three models of vocal tract filtering in bird vocalization. Subfigures are schematic spectrographic representations. In the top row, the frequency ranges of vocal tract resonances are indicated as gray shading. The harmonic sound frequencies produced by the syrinx are indicated as thick lines, continuous if they overlap with vocal tract resonance ranges and dashed if they fall outside these ranges. The bottom row of subfigures shows the sound that is thus emitted from the bird as vocalization for each model. It should be noted that the vocal tract resonance patterns shown are simplified. In reality, the avian vocal tract normally has more than one or two resonance peaks.

vocalizations suggests that parrots indeed use tongue placement to modulate formant patterns independently of syringeal source modulations, which is an interesting extension of the already known parallels between human speech production and bird vocal production.

In conclusion, there are notable differences between vocal production in birds and that in humans, the most important of which relate to the fact that birds have evolved an innovative voice organ that is, at least in songbirds, extremely versatile. Nevertheless, the parallels in basic sound generation mechanisms and a source–filter system are equally notable. This is especially true for species that use vocal tract filtering to create complex modulation patterns independently of the voice source, a fundamental mechanism in coding information in human speech.

Voegelin, Charles Frederick (1906–1986) and Voegelin, Florence Marie (1927–1989)

B L Pearson, Bloomington, IN, USA

Crown Copyright © 2006 Published by Elsevier Ltd. All rights reserved.

Charles Frederick Voegelin was born on January 14, 1906, in New York City and died on May 22, 1986, in Honolulu, a scant four months after celebrating his 80th birthday. He customarily signed his publications using the initials C. F. rather than his full name but was fondly known to friends and colleagues simply as 'Carl.'

After graduation from Stanford University in 1927 with a degree in psychology, Voegelin turned to anthropology for graduate work, studying under Alfred Kroeber at Berkeley and completing his doctorate in 1932 with a dissertation on Tübatulabal, a native language of northern California. This began his lifelong commitment to fieldwork on American Indian languages.

Voegelin held postdoctoral fellowships at Yale University (1933), the American Council of Learned Societies (1934), and the National Research Council (1935). During this period he had close association with Edward Sapir and took courses under Franz Boas and Ruth Benedict. He accepted a faculty appointment at DePauw University in Indiana in 1936, where he remained for five years, teaching and continuing fieldwork before accepting a position in anthropology at Indiana University in 1941. He remained at Indiana until his retirement in 1976.

At Indiana, Voegelin became chairman of the newly created anthropology department in 1947, a post he held until 1966. During these years he encouraged formation of an interdisciplinary program in linguistics (1945) and creation of a separate department of linguistics (1963). At the same time, he remained firm in his support of ties between anthropology and linguistics, even as the two disciplines sometimes diverged in the second half of the 20th century.

Voegelin's major contributions to 20th-century linguistics stem from his editorship of the *International Journal of American Linguistics* (*IJAL*), beginning in 1944. The journal, founded by Boas in 1917, had been without an editor or home base following Boas's death in 1942. Voegelin brought *IJAL* to Indiana University, arranged financing through the university, and served as editor from 1944 until 1980, four years after his retirement and nearly a decade after publication of the journal was shifted from Indiana to the University of Chicago Press. During his 36 years as editor he played a major role in promoting the study and documentation of native American languages.

A significant portion of his work was in collaboration, first with Erminie Wheeler Voegelin (1903–1988), and later with Florence Robinett Voegelin (1927–1989). While at Berkeley, Voegelin met Erminie Wheeler, also a graduate student under Kroeber. They married and began a professional collaboration that lasted until their divorce in the early 1950s. Together they published a revision of Edward Sapir's map of North American Indians in 1944. After their divorce, she continued a distinguished independent career, concentrating on history and ethnology, writing extensively on the history of Indian tribes in the Ohio Valley and Great Lakes region, and serving as editor of *Ethnohistory* from its founding in 1954 until 1964.

In 1953, Voegelin began a collaboration with his second wife, fellow linguist Florence Marie Robinett. She was born on September 26, 1927, in Colorado Springs and died on January 9, 1989. After completing her undergraduate degree at Colorado State College of Education in 1949, she taught for two years in Puerto Rico, then entered the graduate program in linguistics at Indiana University. She completed her Ph.D. with a dissertation on the Hidatsa language in 1954, the same year that she and Voegelin were married.

By this time Voegelin had started the Archives of Languages of the World, with Florence Voegelin in charge. As an outgrowth of the Archives project, she founded *Anthropological Linguistics* and served as editor (1959–1981), continuing as coeditor from 1964 to 1988.

In their work together, the Voegelins prepared an exhaustive catalog of languages of the world, which was published in 20 fascicles in *Anthropological Linguistics* (1964–1966), supplemented by a revised map of the Indian languages of North America. The map, definitive at the time, is the forerunner of the 1999 classification and map prepared by Ives Goddard of the Smithsonian Institution.

Living and working in Indiana, it was natural for Voegelin to develop an interest in the native languages that had been spoken in the state. Of these, he examined Delaware and Shawnee closely while continuing fieldwork on other languages, including Blackfoot, Hidatsa, Hopi, Iowa (Iowa-Oto), Ojibwa, and Penobscot. He encouraged his students to investigate numerous other languages, and through their work and his other contacts he gained a broad overview of the language situation in native America. He was a frequent lecturer at linguistic institutes, conducted numerous field methods courses, and served in 1954 as president of the Linguistic Society of America.

In connection with his work on the Delaware language, Voegelin lent his expertise to authentication of the *Walam Olum*, a purported migration account of the Delaware Indians consisting of glyphs inscribed on wooden sticks and accompanied by a Delaware text. Constantine Rafinesque, who claimed to have obtained these materials in 1820, published a translated version in 1836. The *Walam Olum* has had its supporters and detractors ever since. However, the consensus of modern scholars is that the *Walam Olum*, charming as it may be, is a clever forgery concocted by Rafinesque.

Voegelin read widely and kept abreast of linguistic theory, publishing over 200 articles and reviews in addition to book-length monographs. As editor of *IJAL,* he published reviews by Noam Chomsky at a time when Chomsky's work was not being well received by other editors. Voegelin's own review of *Syntactic structures* saw Chomsky as raising "a single overarching question: how the low number of languages being deeply analyzed in the present day world (and the high number of languages in the world which still remain to be studied) may be approached through the new theory (if it is new). . . ."

Voegelin's prose style, while often ponderous, was nonetheless tolerated by students and colleagues, much as they accepted his challenge to document, analyze, and classify native languages of substantial complexity.

Vogt, Hans (1903–1986)

E Hovdhaugen, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

Hans Kamstrup Vogt was born in Fredrikstad, Norway, but went to high school in France. He studied classical philology, comparative philology, and general linguistics in Oslo and Paris. After finishing his M.A., he returned to Paris to study Armenian philology and started to learn Georgian from Georgian immigrants in Paris. In 1932, after having published a few articles on Armenian syntax and language contact in Caucasus, he got a scholarship to study Georgian in Tbilisi. In 1936, after he returned home, he published his Ph.D. thesis, 'Esquisse d'une grammaire du géorgien moderne' (revised edition, 1971).

Vogt then spent a year (1937–1938) at Yale University, where he studied American Indian languages (among his teachers was Edward Sapir), and he did field work on the Kalispel language (Kalispel-Pend d'Oreille, state of Washington), which resulted in his book *The Kalispel language* (1940).

In 1946, in Oslo, Vogt became professor of Romance philology – a field in which he had no scholarly publications. His qualifications were his publications in general linguistics and his almost native command of French. In 1962 Vogt became professor of general linguistics in Oslo.

Besides numerous minor studies on Georgian, Old Armenian, Ossetic (Ossetian) and Caucasian linguistics in general (Vogt, 1988), Vogt's main contribution to linguistics after the war was his work on the rediscovered Northwest Caucasian language Ubykh. His *Dictionnaire de la langue Oubykh* (1963) was a major contribution to the documentation of this then dying, now dead language. Ubykh has one of the largest set of phonemes known in human languages and accordingly is of great interest to phonological theory.

As a professor of general linguistics, Vogt preferred to give courses in Georgian, Armenian, and other

In 1932, after having published a few articles on Armenian syntax and language contact in Caucasus, he got a scholarship to study Georgian in Tbilisi. In 1936, after he returned home, he published his Ph.D. thesis, 'Esquisse d'une grammaire du géorgien moderne' (revised edition, 1971).

Vogt then spent a year (1937–1938) at Yale University, where he studied American Indian languages (among his teachers was Edward Sapir), and he did field work on the Kalispel language (Kalispel-Pend d'Oreille, state of Washington), which resulted in his book *The Kalispel language* (1940).

In 1946, in Oslo, Vogt became professor of Romance philology – a field in which he had no scholarly publications. His qualifications were his publications in general linguistics and his almost native command of French. In 1962 Vogt became professor of general linguistics in Oslo.

Besides numerous minor studies on Georgian, Old Armenian, Ossetic (Ossetian) and Caucasian linguistics in general (Vogt, 1988), Vogt's main contribution to linguistics after the war was his work on the rediscovered Northwest Caucasian language Ubykh. His *Dictionnaire de la langue Oubykh* (1963) was a major contribution to the documentation of this then dying, now dead language. Ubykh has one of the largest set of phonemes known in human languages and accordingly is of great interest to phonological theory.

As a professor of general linguistics, Vogt preferred to give courses in Georgian, Armenian, and other

Caucasian languages and rarely gave lectures on general linguistic topics or linguistic theory, except at the elementary level. He had very little supervision, and most of his time he was occupied with administrative duties as rector of the university and member and chairperson of important government committees. As a teacher, Vogt did not try to influence the theoretical orientation of his students. Himself a structuralist, he had no objections if others chose different approaches. His courses in Caucasian languages and his descriptive studies inspired the few students he had to pursue Caucasian studies and/or descriptive linguistics studies within a structuralistic frame.

Introduction

Over the last decade, speech synthesis (Nussbaum, 2005) has come a long way toward producing higher-quality, more natural-sounding output. The two most important reasons for this paradigm shift are: (1) computers are now powerful enough to employ sophisticated data-driven techniques such as unit selection (e.g., Hunt and Black, 1996), and (2) better software tools are now available that allow for faster and cost-effective creation of new TTS voices (Ostendorf and Bulyko, 2002).

The advent of high-quality text-to-speech (TTS) may have created the false notion of speech synthesis being a 'solved problem,' that is, the idea that speech synthesis can replace a live human speaker (or a speaker's recording) in any application, service, or product. This is definitely not the case, given the enormous richness and expressive capabilities of the human voice that are impossible, or at least impractical, to match with a speech synthesizer. What unit selection speech synthesis can do, however, is deliver surprisingly good-quality speech for somewhat narrow applications, such as travel reservations, weather reports, etc. (Schweitzer *et al.*, 2003). This high quality is achieved by recording special domain voice databases. For a given domain (e.g., 'travel'), voice talents are being recorded while reading examples from that domain, such as 'Your flight to <destination> has been confirmed.' The idea is to cover as much material as possible that is well suited for the given application. Also, the reading style used (e.g., friendly but affirmative) has to be appropriate for the application. What unit-selection TTS cannot do today (at least not in any practical way) is to turn an average voice, reading in a 'newsreader' (i.e., reserved, toned-down) style, into a highly desirable 'spokesperson' voice for marketing a new product (i.e., speaking in a highly expressive, enthusiastic style). The reason for this inability is simple: there is no way that all the necessary speech data (many hundreds of hours) can be recorded from one single speaker, given the time it would take and the fact that a speaker's voice might change over time. Consequently, modifying recorded speech by signal processing is the only practical option.

This article is organized as follows. In the next section, we will review some of the algorithms available for modifying speech signals in pitch, durations, and other characteristics. The third section will highlight methods available for modifying voice characteristics with the goal of either changing speaking style or even speaker identity. Finally, in the last section, we conclude with a summary and an outlook at future developments.

Voice Signal Modification in Concatenative Speech Synthesis

Concatenative speech synthesis uses snippets (units) of recorded speech, usually cut from full sentences.

Introduction

Over the last decade, speech synthesis (Nussbaum, 2005) has come a long way toward producing higher-quality, more natural-sounding output. The two most important reasons for this paradigm shift are: (1) computers are now powerful enough to employ sophisticated data-driven techniques such as unit selection (e.g., Hunt and Black, 1996), and (2) better software tools are now available that allow for faster and cost-effective creation of new TTS voices (Ostendorf and Bulyko, 2002).

The advent of high-quality text-to-speech (TTS) may have created the false notion of speech synthesis being a 'solved problem,' that is, the idea that speech synthesis can replace a live human speaker (or a speaker's recording) in any application, service, or product. This is definitely not the case, given the enormous richness and expressive capabilities of the human voice that are impossible, or at least impractical, to match with a speech synthesizer. What unit selection speech synthesis can do, however, is deliver surprisingly good-quality speech for somewhat narrow applications, such as travel reservations, weather reports, etc. (Schweitzer *et al.*, 2003). This high quality is achieved by recording special domain voice databases. For a given domain (e.g., 'travel'), voice talents are being recorded while reading examples from that domain, such as 'Your flight to <destination> has been confirmed.' The idea is to cover as much material as possible that is well suited for the given application. Also, the reading style used (e.g., friendly but affirmative) has to be appropriate for the application. What unit-selection TTS cannot do today (at least not in any practical way) is to turn an average voice, reading in a 'newsreader' (i.e., reserved, toned-down) style, into a highly desirable 'spokesperson' voice for marketing a new product (i.e., speaking in a highly expressive, enthusiastic style). The reason for this inability is simple: there is no way that all the necessary speech data (many hundreds of hours) can be recorded from one single speaker, given the time it would take and the fact that a speaker's voice might change over time. Consequently, modifying recorded speech by signal processing is the only practical option.

This article is organized as follows. In the next section, we will review some of the algorithms available for modifying speech signals in pitch, durations, and other characteristics. The third section will highlight methods available for modifying voice characteristics with the goal of either changing speaking style or even speaker identity. Finally, in the last section, we conclude with a summary and an outlook at future developments.

Voice Signal Modification in Concatenative Speech Synthesis

Concatenative speech synthesis uses snippets (units) of recorded speech, usually cut from full sentences.

Commonly employed units are diphones (bracketing exactly one phone-to-phone transition, starting from the spectrally stable middle region of one phone to the spectrally stable middle region of the next phone), or demisyllables (comprising consonants and vowels). At synthesis time, the unit inventory (voice database) is searched for the optimal sequence of units that make up the desired speech output.

Until about a decade ago, typical concatenative speech synthesizers for English used inventories of between 1500 and 3000 units total. Besides special cases such as /r/-colorization of neighboring vowels, mostly single prototypical instances for any given kind of unit were stored in the inventory, predominantly for reasons of storage restrictions and synthesis speed. (Colorization is the influence of the sound of interest [here, /r/] on neighboring sounds. For instance, formant frequencies of vowels immediately preceding or following an /r/ are influenced by it.) Clearly, having just one or, at most, very few candidates to chose from for a specific time slot necessitates modification of the unit by mean of signal processing (e.g., in terms of pitch, duration, and amplitude) in order to 'fit' it in with its neighbors. Note also that the initial selection of the one (or the few) prototypical examples of each class of units to be included in the inventory is a critical process that has much influence on the quality of the synthesized speech (see, e.g., Section 7.3.3 in Olive *et al.*, 1998).

More recently, Unit Selection Synthesis (USEL) (Sagisaka *et al.*, 1992; Black and Taylor, 1994; Hunt and Black, 1996; Conkie, 1999) moved the selection process from the off-line (synthesizer design) phase to the on-line (actual time of) synthesis when the sentence to be synthesized is known. USEL takes advantage of the more powerful computers available to store and search hundreds of thousands of units in total, narrowing down to at least a dozen or so potential candidates for each time slot. Although the availability of several choices (e.g., with different pitch values) reduces (and sometimes eliminates) the need for signal processing, we will see that it is still needed because recording an inventory that covers all potential needs is highly impractical.

Necessity of Voice Signal Modifications

In a keynote paper at the 1997 Eurospeech conference, Jan van Santen (1997) presented far-reaching statistical results that support the importance of voice signal modifications. For example, to cover all combinations of prosodic units in a random test set of sentences with probability 0.75, the inventory size needed to be 150 000 diphone units. He also showed that the similarity of test (i.e., actual usage) and training (unit inventory) text corpora in terms of triphone and vocabulary distributions have a significant impact on this kind of inventory coverage. He concluded that learning algorithms for training TTS systems (such as used in training unit selection paradigms) need to employ solid generalization capabilities to make up for the rather poor coverage of even very large training corpora. This means that the system can cope robustly with unit combinations that are needed to synthesize specific output text but that have not been part of the training set. Note that, so far, the argumentation used mainly the combinatorics of language. However, another way to approach the problem would be to estimate total inventory size based on assumptions of token multiplicity in terms of variations in pitch and durations (amplitude variations left aside for now). Assuming, for illustration purposes only, 2000 unit types with voiced speech and a multiplicity of 20 for pitch variations and another factor of 10 for durational variations, we arrive at $2000 \times 20 \times 10 = 400\,000$ unit tokens that would be needed. This calculation assumes no signal processing is used to change pitch and durations. Traditional diphone-based synthesizers may be considered as existence proofs that signal processing is helpful (here: reducing the inventory back down to 2000 unit types), although it seems that the reduced inventory size surely would come with the cost of lost naturalness when compared to large inventory unit selection synthesizers.

One way to reduce unit inventory size significantly is to use smaller base units. Conkie (1999) proposed using half-phones (about $2 \times 50 = 100$ types for English). A half-phone cuts a diphone at the phone boundary that it contains. Consequently, two half-phones can form a diphone. For the scenario discussed earlier, the statistical advantage of using half-phones over a full set of diphones is based on the fact that the number of necessary unit tokens in the inventory without using any signal processing would be $100 \times 20 \times 10 = 20\,000$, which is a much more manageable set.

From these considerations, it should be clear that signal modifications in terms of pitch and durations should be useful for reducing the inventory size down to practical (i.e., recordable with one voice talent) levels. However, it is also clear that too much signal processing tends to decrease the quality of synthetic speech (Jilka *et al.*, 2003). For pitch, the limit might be 10 to 20%, for durations, perhaps 50%, given available signal processing methods. Generally, the objective should be to maximize quality while balancing inventory size, amount of signal processing used, and last but not least, choosing the specific algorithms that allow for relatively large

Figure 1 Block diagram of LPC synthesis. Periodic pulses with pitch period T are used for voiced excitation. Gaussian noise of unit amplitude is used for unvoiced excitation. The excitation is scaled in amplitude by gain factor σ.

signal modifications with no perceivable quality degradation.

Methods for Modifying Voice Signals

One of the key issues in concatenative speech synthesis is picking the specific speech signal representation (parameterization) for efficiently storing the inventory units, smoothing over concatenation points, and prosody modification. The question of which speech representation to use is tightly related to the question of which algorithm to use for prosody modifications. Therefore, the ideal method for modifying voice signals for speech synthesis purposes meets the following objectives:

1. It employs a speech representation that enables transparent (inaudible distortions) encoding/decoding. When signal characteristics are being modified, the result has to sound convincingly like it has been produced by the recorded voice talent using different characteristics (e.g., pitch, duration).
2. The speech representation needs to allow random access to any indexed inventory unit without large computational costs for switching from one unit to another. For speech representations with memory (e.g., filters), this encompasses also storing algorithm-internal state variables, plus appropriately smoothing over the transition.
3. Although not a strict requirement, choosing a speech representation that adds compression has the practical advantages of a smaller inventory file size (i.e., more recorded speech per megabyte of disk storage) that makes distribution of voice inventories and TTS server maintenance easier.

In the following, we will highlight the basics of the three most commonly used methods: (1) linear prediction coefficients (LPC) and their role in capturing spectral envelopes in close correspondence to vocal tract geometry, (2) time-domain pitch synchronous overlap add (TD-PSOLA) as a low complexity method for pitch and durational changes, and (3) sinusoidal speech representations, enabling more sophisticated speech modifications.

Linear Prediction A linear prediction filter of integer order p defines the output signal $y(n)$ (here: synthesized speech) as the result of an excitation signal $x(n)$ filtered by a recursive (autoregressive) filter $a(k)$:

$$y(n) = x(n) + \sum_{k=1}^{p} a(k)y(n-k) \qquad (1)$$

It can be shown (e.g., Markel and Gray, 1976, see Figure 4.1) that the filter coefficients $a(k)$ represent a vocal tract model comprised of p sections of an acoustic tube of stepwise constant cross-sectional areas. Wave propagation in the tube is assumed to be without losses, and one-dimensional (plane), and tube walls are assumed to be rigid. Any side branch (e.g., nasal tract) is not part of the model.

In the simplest version of LPC-synthesis, the excitation signal $x(n)$ is either a train of pulses or white Gaussian noise (see Figure 1). The pulse train approximates the glottal excitation for voiced sounds, whereas the white Gaussian noise represents the turbulent noise that excites the vocal tract for unvoiced sounds. Note that, both the noise and the (single) pulse excitation are assumed to have a flat (over frequency) spectrum. Note also that, the LPC filter gives the synthetic speech the desired spectral envelope (approximating the spectral envelope of human speech and matching its formants), whereas the simplistic pulse/noise excitations clearly fail to match spectral details.

Figure 2 Time-Domain Pitch-Synchronous Overlap-Add (TD-PSOLA). Reproduced from Dutoit T (1997). *An introduction to text-to-speech synthesis.* Boston: Kluwer Academic Publishers, with kind permission of Springer Science and Business Media.

LPC synthesis as described so far violates property 1 stated earlier. LPC synthesis clearly sounds 'buzzy' (due to the repetitive nature of the pulses that do not match the spectral details of human glottal excitation) and, hence, is not transparent as a speech presentation. However, because of its relationship to vocal tract geometry, LPC lends itself to spectral modifications that are based on geometric differences of vocal tracts (e.g., male to female speech conversion, see Voice Alteration section). Improvements to speech quality can be achieved by using more sophisticated models of the excitation, such as glottal pulse models (see Olive *et al.*, 1998, Section 7.4.3; also see multipulse models, Caspers and Atal, 1987). In any case, it should be obvious that pitch can be modified by changing the pulse rate of the excitation, and durations can be modified by changing the updated rate of the LPC filter coefficients during synthesis. Also, smoothing of the filter can be used to achieve better concatenation between units.

Time Domain Pitch Synchronous Overlap Add (TD-PSOLA) An intriguingly low-complexity way of modifying pitch and duration of recorded speech was introduced in Moulines and Charpentier (1990). The basic idea is outlined in Figure 2.

The left column of Figure 2 shows time-domain speech waveforms and the right column shows spectra related to the waveforms on the left. For voiced speech as depicted in the top row, we recognize the quasiperiodic waveform that gives rise to the comb-filter-like fine structure that is visible in the spectrum depicted on the top right.

In the second row of graphs in Figure 2, four separate waveforms have been extracted. Each of them encompasses L = two pitch periods and has been tapered with a Hanning (raised squared cosine) window so the waveforms build up and die down gradually. Note also that, the individual waveforms have been repositioned in time relative to each other. The right panel in the second row shows the spectrum of one of the individual waveforms. Very little of the harmonic structure remains visible.

Finally, in the third row in Figure 2, we see the result of adding the individual waveforms in their new positions in time. In this example, the outcome is a speech signal of lower pitch and longer duration. The related spectrum on the right shows the harmonic structure of that lower pitch.

Higher pitches can be achieved by staggering the individual waveforms closer together in time before adding them up. Shorter durations are achieved by dropping individual waveforms, whereas longer durations are achieved by repeating individual waveforms as needed. Finally, note that the Hanning window has the convenient property that it reproduces the original speech signal when no modifications of pitch or durations are performed.

Although the TD-PSOLA method may be applied to the speech signal itself, a possible variant would be to apply it to the so-called LPC-residual. The LPC residual is the specific excitation signal $x(t)$ in Eq. (1)

that would be needed to match the original speech exactly with the synthetic output $y(t)$. The LPC residual can be obtained by inverse filtering of the speech signal. Inverse filtering has the effect of 'whitening' the individual waveforms used in TD-PSOLA. Combining the LPC and TD-PSOLA methods this way also allows for spectral envelope smoothing between inventory units. For time-scale modifications without any pitch modification, the so-called WSOLA approach may be used (Verhelst and Roelands, 1993).

Sinusoidal Representations The main drawback of the simplest form of LPC synthesis is its crude representation of the glottal excitation signal. On a frame-by-frame basis, that is over 5–50 ms intervals, the amplitude and phase relationships of the first few harmonics may contain crucial information on speaker identity (independent of the supersegmental prosodic and phonetic cues). Therefore, sinusoidal speech representations can be viewed as a more sophisticated means to meet the transparency requirement stated in the beginning of this section. As with TD-PSOLA, we have the choice of including LPC filtering to allow for vocal-tract geometry motivated modifications of the spectral envelope and for its smoothing at concatenation points. Different from TD-PSOLA, however, pitch modifications are done in the frequency domain, by compressing or stretching the spectrum. Slowing down and speeding up depends on the parameter update rate.

For the following, we chose to follow the pioneering work of Quartieri and McAulay (1992). Let $s(t)$ be a signal of interest, either speech or LPC residual, then

$$s(t) = \sum_{l=1}^{L(t)} A_l(t)\cos[\Omega_l(t)],$$

with

$$\Omega_l(t) = \int_{t_l}^{t} \omega_l(\sigma)d(\sigma) + \phi_l \qquad (2)$$

where $A_l(t)$ is the slowly time-varying amplitude of the l-th sine wave, $\Omega_l(t)$ its instantaneous phase, ω_l the radian frequency of the l-th sine wave, and ϕ_l its phase. The analysis task is comprised of estimating harmonic frequencies and phases. Potential problems are the 'birth' and 'death' of specific sinusoids and the representation of unvoiced speech.

Several variants of the sinusoidal approach exist. One is the HNM (Harmonic plus Noise Model) representation (Stylianou, 1996; Kain and Stylianou, 2000) that splits the speech spectrum into a low-frequency voiced part that is modeled by the sinusoidal approach and a high-frequency unvoiced part that represents the more noiselike characteristic of speech spectra at high frequencies. The 'maximum voiced frequency,' which is the cutover frequency between the two representations, may be a fixed frequency or may be set once for each speaker individually or may be even updated over time or dependent on the specific speech sound. Another approach is STRAIGHT (Kawahara *et al.*, 1999), where special care is given to estimating the harmonic amplitudes accurately (bias-free). Both HNM and STRAIGHT, however, assume that all sinusoids are at frequencies that are integer multiples of the fundamental frequency of the signal. For practical applications in speech synthesis, the reader should be aware of the fact that specific speakers' voices may be less suitable for sinusoidal speech representations than those of other speakers. For a 'bad' speaker, the coded/decoded speech may sound somewhat busy or metallic, which is in clear violation of the transparency requirement.

Modification of Voice Characteristics

Variability in speech has several dimensions, the most important ones for speech synthesis purposes being speaker variability, linguistic variability (inter- and intraspeaker), and task variability. The acoustic correlates of these dimensions are variations in pitch, duration, amplitude, and spectrum. We already discussed how to change these low-level attributes with the exception of spectral characteristics.

In the following, we will focus on higher-level applications of signal processing that are used to change voice characteristics on a more global scale. Among these applications are modifications to speaker identity (voice transformation, voice alteration targeted at changing gender, individual differences, or even dialect) and modifications to speaking style and/or emotions for a given speaker (changing emotions or adapting the speech to fit environmental needs such as Lombard speech (Pisoni *et al.*, 1985) that is appropriate for noisy environments). Although the algorithms used may serve both classes of applications, there are important differences between the two. Changing the speaker identity can leverage the significant effort that went into creating one high-quality TTS voice for the purpose of being able to offer several such voices, but modifying intraspeaker characteristics such as speaking style or emotion avoids the efforts of having to rerecord large parts of an existing voice database with the same speaker, each time using a different speaking style or emotion.

In order to mimic real-life variability of speech with a synthesizer, it is helpful to list different speech

Figure 3 Second and third formant frequencies for the vowel /u/ by dialect and gender. (Ann Syrdal, priv. comm.)

and speaker characteristics that might be changed by signal processing. Linguistic variability encompasses variations due to intonation plus the fact that phonemes may also have different spectral properties depending on context (coarticulation), speaking style/emotion, and speaker. Gender differences include the fact that average pitch and formant frequencies are higher for females than for males. Dialect differences consist of the use of different phonemes for a word and the use of different allophones for the same phoneme in a given context, plus differences in prosody. As an example, Figure 3 shows data for male and female second- and third-formant frequencies depending on the dialect of U.S. English for the vowel /u/ (Syrdal, 1996). Some of the variability of speech between individuals clearly has reasons that can be traced to differences in vocal tract geometry. Consequently, spectral (vocal-tract motivated) changes, as well as 'individualized' prosody models that capture a specific speaker and/or emotion/speaking style are being summarized next.

Spectral Models for Changing Speaker and/or Speaking Style

Here, we outline methods for transforming speech of one speaker either to sound like speech from another speaker or to sound like speech of the same speaker, but in a different speaking style or with different emotions. We focus primarily on vocal-tract-related characteristics of speech but note that the basic concepts also apply to representations of the glottal excitation.

Acoustic correlates of speaker individuality can be found in vocal-tract formants, spectral tilt, and glottal characteristics. One obvious way to try to map 'source speech' (what we have) with a certain set of characteristics (e.g., speaker identity, etc.) to 'target speech' (what it should sound like) with another set of characteristics is to use two codebooks of vector-quantized spectral (e.g., LPC) vectors, each trained on one of the two sets, and find a mapping between corresponding codebook entries. This technique was pioneered by Abe at NTT in Japan (Abe *et al.*, 1990) using parallel corpora, source set A and target set B, comprised of identical sentences. A challenge with this approach is the time alignment of vectors from one set with the corresponding vectors from the other. Although ideally the same material is recorded in both corpora, it is not always straightforward to map speech frames even for a given single word, in particular when two different speakers spoke the word, because of differences in vowel reductions, phone omissions or additions, or other individual pronunciation differences. Dynamic Time Warping (DTW) is used to establish this correspondence, and histograms of these correspondences serve as weights for the mapping function:

$$S_i^{(A\to B)} = \frac{\sum_{j=1}^{J} W_{ij} S_j^{(B)}}{\sum_{j=1}^{J} W_{ij}} \tag{3}$$

Here A and B represent source and target sets, respectively, $S_i^{(A\to B)}$ is the i-th spectral vector of the mapped source codebook, and w_{ij} are the histogram counts of how often vector i of codebook A was found to correspond to vector j in codebook B, itself containing J vectors $S_i^{(B)}$. Note that, Eq. (3) can be viewed as an interpolation between different target spectral vectors. Therefore, it is important to choose a representation $\mathbf{S}$ where linear interpolation makes sense and does not lead to 'oversmoothing.'

Another way to map features from a source corpus to those of a target corpus is to estimate an appropriate transformation function. The most popular method for doing this is based on Gaussian Mixture Models (GMMs). One of the early adopters of GMM-based methods for voice conversion is Stylianou (1996).

Let ω_m denote the m-th acoustic class out of a total of M classes. In a Gaussian mixture density model, the probability density functions of any of the K observation vectors $\mathbf{X}_k (k = 1, ..., K)$ is given by:

$$p(\mathbf{X}_k) = \sum_{m=1}^{M} P(\omega_m) p(\mathbf{X}_k|\omega_m) = \sum_{m=1}^{M} c_m N(\mathbf{X}_k, \boldsymbol{\mu}_m, \boldsymbol{\Sigma}_m) \quad (4)$$

where x_k is a L-dimensional random vector. The conditional probability density for each of the M classes ω_m is assumed to be a Gaussian component density $N(\mathbf{x}_k, \boldsymbol{\mu}_m, \boldsymbol{\Sigma}_m)$, and the c_m's (the probabilities for classes ω_m) are the related normalized mixture weights ($\Sigma_{m=1}^{M} c_m = 1$). Each L-variate Gaussian component density is of the form:

$$N(\mathbf{X}_k, \boldsymbol{\mu}_m, \boldsymbol{\Sigma}_m) = \frac{1}{(2\pi)^{\frac{L}{2}} |\boldsymbol{\Sigma}_m|^{\frac{1}{2}}} \times \exp\left[-\frac{1}{2}(\mathbf{X}_k - \boldsymbol{\mu}_m)' \boldsymbol{\Sigma}_m^{-1} (\mathbf{X}_k - \boldsymbol{\mu}_m)\right] \quad (5)$$

Here $\boldsymbol{\mu}_m$ is an L-dimensional mean vector for the m-th component, and $\boldsymbol{\Sigma}_m$ is its covariance matrix. Therefore, the m-th mixture component is characterized by its center (the mean) and the spread around that center, expressed by the covariance matrix. Note that Eq. (4) expresses arbitrary distributions as a linear combination of Gaussians. If we associate the m-th component with a specific acoustic class (e.g., nasals, vowels), it should be intuitively clear that mapping techniques based on Eq. (4) are more robust than those based on Eq. (3) that do not explicitly distinguish between different acoustic classes while also lacking an inherent model (here Gaussian) for generalizing to unseen data.

In estimating a mapping $\mathbf{F}_x(\mathbf{X})$, the goal is to minimize the mean-squared error between the transformed set $\tilde{\mathrm{Y}} = \{\tilde{y}_k = \mathbf{F}_x(\boldsymbol{X_k}), \boldsymbol{k} = 1 \ldots K\}$ of source data and the training set $\mathrm{Y} = \{y_k, k = 1 \ldots K\}$ of target data. Again, we assume that both sets of observation vectors are time-aligned using DTW.

Furthermore, let $h_m(\mathbf{X}) = P(\omega_m|\mathbf{X})$ be the conditional probability of $\mathbf{X}$ belonging to class ω_m, and, using Eq. (4) and Bayes' rule, we find:

$$h_m(\mathbf{X}) = P(\omega_m|\mathbf{X}) = \frac{P(\omega_m) p(\mathbf{X}|\omega_m)}{p(\mathbf{X})} = \frac{c_m N(\mathbf{X}, \boldsymbol{\mu}_m, \Sigma_m)}{\sum_{i=1}^{M} c_i N(\mathbf{X}, \boldsymbol{\mu}_i, \boldsymbol{\Sigma}_i)} \quad (6)$$

The conversion function $\mathbf{F}_x(\mathbf{X})$ is chosen to be of the form

$$\mathbf{F}_x(\mathbf{X}) = \sum_{m=1}^{\mathbf{M}} \mathbf{h}_m(\mathbf{X}) \left[\mathbf{v}_m + \boldsymbol{\Gamma}_m \boldsymbol{\Sigma}_m^{-1} (\mathrm{x} - \mu_m)\right] \quad (7)$$

The unknown L-dimensional vectors υ_m and the unknown $L \times L$ matrices $\boldsymbol{\Gamma}_m$ are obtained by solving normal equations for the least-squares problem between $\mathbf{Y}$ and $\tilde{\mathbf{Y}}$. Details can be found in Stylianou (1996). Note also that the method can be improved further by basing the conversion function on joint source and target densities (Kain and Macon, 1998) instead of basing them solely on source densities as outlined earlier.

Most recently, Toda *et al.* (2005) introduced a new statistical method based on maximizing the likelihood (ML) function $\log p(\mathbf{y}, \mathbf{x})$ for each class (mixture component). This leads to a generalization of the mean vectors $\boldsymbol{\mu}$ and covariance matrices $\boldsymbol{\Sigma}$ in the simplified derivation given earlier. Toda also included dynamic aspects (time derivatives) of features to exploit their trajectories over time. Both measures led to less 'erratic' feature trajectories of the transformed speech when compared to the basic GMM method while keeping the global variance (observed over time) as high as in the recorded target speech (the GMM method usually reduces that variance considerably). The new method also avoids oversmoothing of GMM-converted spectra that sometimes leads to overly broad formants in the converted speech.

Prosody Models and Prosody Changes

Having the ability to change the frame/segment-related signal correlates to prosody, such as pitch, durations, and amplitude, gives us the tool to approach changing prosody aspects of speech on a larger time scale. One purpose of supersegmental prosodic changes is to convey (different) emotions. Another is to indicate topic structure or speech acts and other functional aspects of intonation (Hirschberg, 2004). However, there is evidence that a perfect 'synthetic' copy (i.e., a TTS-based mimic) of a human speaker is only possible with a data-driven prosody model that is trained on the specific speaker. Here the idea is to

enable powerful generalization from sparse training data by capturing the way a specific speaker uses prosody in a specific context (e.g., in a dialog scenario) and for a specific speech act (e.g., greeting) and make the TTS system predict the right prosody so its unit selection module can do a reasonable job of retrieving the correct speech segments and/or help a prosody-modification-enabled back end to do the necessary signal modifications.

Recent developments in prosody models, much as in speech representations (i.e., 'signal models') for speech coding or speech modification purposes, followed a similar trend from 'knowledge-based' to 'data-driven' paradigms (Dutoit, 1997). Knowledge-based systems incorporate the skills and intuition of the researcher. Data-driven models learn from training data. As in many other cases, the 'right' middle ground is to allow for data-driven adaptability/flexibility while basing the models on generally accepted principals for robustness and generalization (van Santen, 1997). Clearly, the future belongs to systems that use machine-learning techniques that are seeded with generally accepted intonation rules.

Intonation, the way we assign fundamental frequencies to voiced signal segments of speech, is an important part of prosody generation. Theories of tone sequences pose hierarchical structure on the problem that may be expressed on a symbolic level in the form of Tone and Break Indices ('ToBI', Silverman *et al.*, 1992). Such a symbolic linguistic representation then needs to be followed by a way of actually assigning fundamental frequency values. An example of an early model for generating actual fundamental frequency contours for synthesis purposes is the Fujisaki model (Hirose *et al.*, 1986). The Fujisaki model basically applies LPC (see earlier) to fundamental frequency contours in that it tries to correlate major intonation events in timing, durations, and amplitudes with linguistically motivated notions of phrase and accents 'commands.' It models these commands as step functions and then filters these 'excitation' signals by an LPC-like smoothing filter to arrive at a fundamental frequency contour for a whole utterance.

A second way to build an intonation model is to identify proper 'building blocks' of intonation in the form of stylized fundamental frequency (F_0) tracks and to associate each of these tracks with the terminal leaves of a Classification and Decision Tree, such as CARTs or via neural networks (for details, see, e.g., Section 6.9.2 in Dutoit, 1997). Such representations are driven by syntactic features provided by automatic text analysis or (manual) markup.

Most recently, ways have been found to exploit directly the large speech databases recorded with a single speaker for unit-selection synthesis. Here, the idea is to search the database for a reasonable prosody match at the symbolic level and harvest appropriate F_0 tracks (Huang *et al.*, 1997). Challenges of this method include the sparseness of the data even existing in a large speech database and how to fill in the 'holes.' Different ways to fall back to fundamental knowledge-based rules exist.

Any of the parametric intonation/prosody models just discussed can be employed within the signal transformation framework discussed earlier. For convincing results, the feature vectors x and y of that framework have to include model parameters of the chosen prosody model or representation.

Voice Alteration

Voice alteration is the task of changing ('disguising') a source speaker's voice so he/she can no longer be recognized without actually trying to match any peculiar target speaker. Such capability is useful for speech synthesis purposes because any 'new' voice obtained through speaker alteration helps in marketing of a TTS system.

In addition to changing pitch as discussed previously, changing the vocal tract size is helpful. Starting from a male voice database, for example, raising the pitch and shortening the vocal tract may simulate a female or child voice. Several methods are available to achieve such alteration. One specific method summarized here exploits the fact that Linear Prediction Coefficients (LPCs, see Linear Prediction section) can be converted to log (pseudo) areas that define a corresponding acoustic tube. Scaling that tube and converting back to LPCs results in voice alteration.

It can be shown (e.g., Markel and Gray, 1976, section 5.5.2) that stable filter LPCs can be converted into reflection coefficients $r(k), k = p,\ p-1, \ldots, 1$, by starting a backward recursion with initial LPCs $b_{p,0} = 1$, $b_{p,1} = a_1, \ldots, b_{p,p} = a_p$, and setting $r_p = a_p$:

$$\begin{aligned} & b_{k-1,i} = \frac{b_{k,i} - r_k b_{k,k-i}}{1 - r_k^2} \text{ for } i = 0, 1, \ldots, \mathbf{p} - 1 \\ & \text{extract } r_k = b_{k,k} \\ & \text{and check } |r_k| < 1 \end{aligned} \tag{8}$$

If any reflection coefficient has a magnitude that is larger than unity, the corresponding LPC filter is unstable.

From reflection coefficients obtained using Eq. (8), we then compute *L*og *A*reas using

Figure 4 Log areas derived from LPC analysis for the vowel /i/.

Figure 5 Same log areas as in **Figure 4**. However, here the linearly interpolated line segments were 'compressed' along the distance axis, representing a 25% reduction in vocal tract length. The final 'stair case' representation was sampled from the linear segments and then used to resynthesize the vowel.

$$LA_0 = 0$$
$$LA_{k+1} = \log\left(\frac{1 + r_k}{1 - r_k}\right)$$
$$\text{for } k = 1, \ldots p \qquad (9)$$

Figure 4 shows the log areas corresponding to a LPC filter of order $p = 16$ for the vowel /i/. Here, the 17 log areas are shown as represented as sections of the corresponding acoustic tube. Note that, the ubiquitous $LA_0 = 0$ on the left corresponds to the 'lips' (front) whereas LA_{16} on the right corresponds to the 'glottis' (back). Also shown in Figure 4 is a straight-line representation that can be used for interpolating the geometry of the pseudo vocal tract.

Figure 5 shows a pseudo tract that is shortened by 25% by 'compressing' the interpolated straight-line representation and resampling it. Note that, the high-order log areas have been 'extrapolated' to be of the same value as the highest-order original log area. Different, nonlinear stretching or compression schemes are admissible. For example, the 'back cavity' (i.e., pharynx section) could be stretched by a different factor as the 'front cavity' of the vocal tract. Interesting voices can be created easily this way, for example, 'gnome'-like voices for computer games.

Conclusions

In this article, we have highlighted algorithms and techniques to transform speech from one speaker using a specific speaking style and being in a specific emotional state to sound like either a different speaker or to fit a different speaking style or representing a different emotional state. All signal aspects related to all parts of the human vocal apparatus have to be included in order to arrive at high-quality results.

For the low-level signal processing, many algorithms can be borrowed from the most advanced speech coding/compression efforts. Besides the strict requirement of transparency (i.e., nondetectability), speech coding is used to reduce storage requirements, which is essential for distributing and incorporating large voice databases with/into Text-to-Speech systems. Nontraditional requirements of speech coding algorithms and speech representations are related to random access and modification of signal parameters. An important open problem that still needs to be solved is the effective representation and modification/transformation of glottal excitation.

In addition to the basic algorithms for signal modifications, there are higher-level algorithms that capture ('learn') a speaker's speech on several time scales: frames, segments, words, and whole sentences. The reader should expect future research work being applied in even larger contexts like paragraphs and whole 'stories.' For this, advanced machine learning techniques such as Support Vector Machines (Vapnik, 1998) and Boosting (Shapire, 2002) may outperform traditional techniques based on, for example, CARTs.

The most advanced voice modification techniques are still not good enough to deliver convincing 'transformed' speech. With increasing quality, however, the need for extensive and comprehensive recording of voice databases will be reduced to just the 'essentials,' whereas more and more 'derivative' speaking styles, emotions, and/or speakers will be created through modification of a smaller set of original recordings.

Voice Quality

J H Esling, University of Victoria, British Columbia, Canada

© 2006 Elsevier Ltd. All rights reserved.

The term 'voice quality' refers to those features of speech that are present more or less all the time that a person is speaking: the background characteristics perceived as the most constant or persistent over time. Voice quality describes the habitual, long-term features of accent in an individual's speech. It is, perceptually, the longest-term phonetic component, together with 'voice dynamics' features and 'segmental' features, of the aural medium for language (speech). It can either represent characteristics acquired as a part of 'accent,' the regional indicators or social markers of a person's origins, or idiosyncrasies that in their particular and ultimately unique combination signal the identity of an individual speaker. Voice quality or 'voice quality setting' are the general phonetic terms that best correspond to what is widely meant by 'voice' in popular usage, as in the contexts of 'the singing voice' or a professional announcer's voice.

Descriptive Models

Because the term 'voice quality,' like the popular term 'voice,' is often used in its narrowest sense to mean the sound resulting from (or at least perceptually attributable to) the vibration of the vocal folds, the alternative phrase 'long-term quality' has been adopted by some authors (Nolan, 1983). Vocal fold vibration is generally termed 'voicing.' Differences in the 'state' of laryngeal voicing are more precisely termed 'phonation type,' either to characterize the different laryngeal features of contrastive speech sounds or to describe differences in long-term laryngeal sound quality (*see* **States of the Glottis**). Categories of phonation are presented in a descriptive framework by Catford (1977, 93–116) and by Esling and Harris (2005).

First reference to voice quality in modern descriptive phonetic theory is usually attributed to Henry Sweet, whose teaching at Oxford is the purported basis for the character of Professor Higgins in Shaw's *Pygmalion* (see Sweet, 1877). Sweet's 'organic basis' (1890) is used in the sense of the 'long-term quality' specific to a given language and, although appearing to emphasize intrinsic, anatomical origins, it is equivalent to the more extrinsically based term 'articulatory setting' adopted by Honikman (1964) of the London school of Daniel Jones (see later in this article). Abercrombie (1967, 89–95) offers the clearest definition of 'voice quality' within phonetic theory as having a general, relatively nonfluctuating quasi-permanent character, distinguishing it temporally from rapidly fluctuating segmental articulations and from slowly fluctuating dynamic or prosodic patterns (*see* **Prosodic Aspects of Speech and Language**).

Popular descriptive labels for voices are predominantly 'impressionistic' and include such terms as 'sepulchral,' 'muffled,' 'light,' 'metallic' and 'guttural' voice (see Laver, 1979). Because these metaphors have no articulatory phonetic referents, it is of greater value in phonetics to use labels that convey plausible, if not definitive, articulatory origins of the sounds in question. Descriptive phonetic labels can be used systematically and successfully because of the general phonetic principle of the idealized, speaker-independent vocal tract, which assumes theoretically that all normal speakers can imitate the articulations with which different auditory qualities are associated. In the tradition of the Edinburgh school of phonetics, the various characteristics of long-term articulatory setting and of long-term phonation type are referred to as 'voice quality settings,' which together make up the set of features that describes an individual's voice quality (Laver, 1980).

Production and Perception

Production of voice quality is traditionally divided into the two articulatory categories of laryngeal features and supralaryngeal features. Laryngeal features constitute phonation types or settings of the laryngeal musculature that produce an audible quality ranging, for example, from 'breath' to various types of voicing and from 'whisper' to 'creak' to 'harshness.' Supralaryngeal features describe the setting of the vocal tract in its longitudinal and latitudinal dimensions, from the lips to the larynx and including the position of the mandible, the posture of the tongue, and the incidence of nasal resonance (*see* **Phonetics, Articulatory**) for a comparison of the basic series of places of articulation.

As speech is the aural medium for language, by which symbolic sounds are perceived, the specification of long-term voice quality features also hinges on perceptual criteria. The qualification that some speech characteristics are 'more or less' permanent results from the perceptual ambiguity between sounds that are the product of habitual configurations of the vocal tract and sounds that recur frequently over stretches of time. For example, a voice could be perceived as habitually 'nasal' either if velic opening (coupling the oral and nasal cavities) were sufficiently great most of the time to produce persistent nasal resonance, or if

the utterance in question contained a string of nasal consonants or vowels so frequently interspersed that an impression of nasality was dominant over time. A string of uvular or pharyngeal consonants is often salient enough to leave a strong impression of their place of articulation over the long term, even though the articulators may not be maintained in a habitually 'uvularized' or 'pharyngealized' posture during the production of most of the sounds in that stretch of speech. Segments are also variably 'susceptible' to given settings. A superimposed 'velarized' setting, for instance, will appear prominently on a [b] or an [œ] sound but will be indistinguishable on homorganic [g] or [u] sounds, which are already velar and are not susceptible to adventitious velarization.

Due to this temporal interaction, dynamic aspects of speech such as pitch fluctuation, loudness, and tempo may also contribute to perceptions of 'long-term quality.' It is in this sense that some linguists have used terms such as 'vocal qualifier' to refer specifically to features that are likely to change in order to convey paralinguistic meaning (see Crystal, 1969). Furthermore, in perceptual, auditory terms, there is not strictly a one-to-one correspondence between any of the features in the descriptive phonetic taxonomy for voice quality and any single configuration of the vocal tract. For example, settings of the velopharyngeal mechanism are not the only articulatory postures that may produce the auditory impression of nasality. The taxonomy (outlined in Figure 1), is therefore defined according to auditory convention and is based on the phonetician's experience of articulatory imitation and auditory comparison. As a system of labeling, it is clearly subject to revision as new concepts relating salient sounds to their physiological origins are developed.

One easy parametric way to look at voice quality settings is to divide the vocal tract into six configurational regions: lips, tongue, jaw, velic opening, laryngeal constrictor, and glottis. This is done in Figure 1, beginning with settings of the oral vocal tract, leading into settings of the laryngo-pharynx, including the laryngeal constrictor, and finishing with an outline of the specific laryngeal settings known as phonation types, which are generally glottal but are also influenced by the action of the laryngeal constrictor. The more the setting is influenced by the laryngeal constrictor, the more the pitch of the voice plays a role in its auditory perception and categorization. Specifically, the vertical height of the larynx interacts with laryngeal constriction to alter acoustic spectral quality, and the addition of laryngeal constriction contributes whisperiness, creakiness, or harshness to the simple glottal states listed in part (c) of Figure 1. Generally, pitch increases towards the bottom of Figure 1, and the effect of constriction is greatest toward the right.

Functions of Voice Quality

The distinction is often made between 'intrinsic' and 'extrinsic' voice quality, where the former implies anatomically derived features not under the speaker's volitional control and the latter reflects acquired traits characteristic of a particular community (Laver and Trudgill, 1979). Some linguists use the expression 'voice quality,' or the parallel phrase 'voice set,' exclusively in its 'intrinsic' sense (Crystal, 1969). In either case, the role of voice quality is primarily 'indexical' as opposed to 'linguistic' with reference to the kind of meaning that it carries. Whereas shorter-term features of speech, such as segments, convey linguistic meaning, distinguishing minimally between word pairs such as *pat* and *bat*, long-term features are more often subtle indices, or indicators, of physical or psychological characteristics and of regional and social origins. Whereas segmental features tend to be used for linguistic purposes (although they also indicate a considerable amount about the speaker), and voice dynamics features tend to play a more paralinguistic role (although features like intonation can also signal a great deal about regional origin and other demographic traits), voice quality features tend to be extralinguistic (indicating almost exclusively demographic affiliation and personal preferences). The idiosyncratic basis of voice quality depends on accent choices made during language acquisition as well as on the individual speaker's anatomy and physiology, which can be influenced by temporary physical conditions. The task of automatic speaker identification by machine includes the attempt to isolate these individual features, many of which are long-term (*see* **Speaker Recognition and Verification, Automatic**).

Beyond the level of the individual, we are able to tell if a person has a cold, or laryngitis, or various chronic conditions from the often easily recognized long-term features superimposed on the person's normal speech. Within the national community, we can often tell where a person comes from based on the shared voice quality settings peculiar to any given region. Tongue raising (towards the back of the oral cavity) as a habitual secondary articulation in parts of Yorkshire or Lancashire in the north of England is a salient example. Social class is also marked by a preference for particular settings, but these also depend on regional standards of accent. Nasal voice, for instance, carries high social prestige when associated with certain accents (viz., RP, Standard Edinburgh English) but stands out as an undesirable feature to many listeners when associated with other

Figure 1 Descriptive phonetic labels for voice quality settings.

accents (see Esling, 2000). Evaluations of this sort are quite subjective. Tracing the incidence of voice quality features, and people's reactions to them, however, is a valuable tool in sociophonetic research. Language attitudes, and even the desire to modify one's own accent when learning a second language, may be dependent on identities and feelings of self-esteem signaled by differences in voice quality settings.

Paralinguistically, changes in setting over short periods of time give an indication of changing emotional states of the speaker. These are usually referred to as 'register shifts' or 'code switching.' Although some aspects of the vocal expression of emotion may be physiologically universal, our interpretation of subtle vocal cues is culturally conditioned. We may often extend our interpretation of emotion to such a degree that we ascribe fixed psychological traits to a speaker. The cultural context of this kind of prototyping has been explored through phonetic analyses of the production of various voice types by professional voice actors and by evaluating listeners' perceptual responses to a range of vocal character-role portrayals (Teshigawara, 2003).

Analysis of Voice Quality

Auditory analysis of voice quality is used in dialect and sociolinguistic research to identify and describe the indexical features found in pronunciation. It also has been used as a focal point to illustrate differences between languages and as a guide to the learning and teaching of pronunciation. In the specification of voice quality settings that describe a linguistic community, sufficient numbers of subjects, drawn according to sociolinguistic principles of demographic representation, are necessary in order to isolate features common to the group from speaker-specific features (e.g., Stuart-Smith, 1999). In speech pathology and audiology, the taxonomy proposed by Laver *et al*. (1991) has been adopted by many practitioners as an auditory guide. The complex analysis of pathological voice conditions for diagnostic purposes is outlined in Kreiman and Gerratt (2000).

To supplement auditory classification and perceptual evaluation, there are several instrumental techniques that help identify the physiological correlates of voice quality. These include electropalatographic, laryngographic, laryngoscopic (Esling and Edmondson, 2002), cineradiographic, electromyographic, MRI (Teshigawara and Murano, 2004), and aerodynamic techniques. Ideally, actions of the articulators are observed over longer periods of time (30 seconds, for example) than for segmental purposes. Acoustic techniques, including long-term average spectral analysis (Bruyninckx *et al*., 1994), which assesses the distribution of energy peaks in the spectrum integrated over time, are noninvasive and allow large numbers of survey subjects to be studied.

Introduction

Interactive voice response (IVR) systems were one of the first speech technology–based telephony applications to be widely deployed in the United States. In the first IVR systems, the customer employed touch-tone-based input, and the system provided synthetic speech feedback and prompts as output. Such systems are still in wide use today, although automated speech recognition–based IVR systems, in which users respond with speech instead of touch-tone input, have begun to replace the touch-tone-based applications.

One of the first applications to gain wide implementation was voice messaging, which allowed users to manage telephone voice messages. However, this application was quickly augmented with related and much more complex IVR applications designed to provide many types of customer services, including card credit authorization, utilities problem reporting, automatic bill paying, stock quotations, and travel arrangements and travel information, to name a few. The twofold goal of many of these services was to improve customer service while eliminating human customer service representatives, a significant source of costs to businesses.

Industry was quick to see the potential cost-saving aspect of IVR systems, and companies hurried to develop such systems. With the exception of applications developed within the telecommunications industry specifically, little attention was paid to user interface design during application development, and virtually no standardization took place with respect to prompts, assignments of touch-tone keys to various functions, etc. As a result, users never knew what to expect when they encountered an IVR application, and consequently were unable to develop a mental model of IVR applications or to anticipate the responses required to navigate such systems efficiently and effectively.

Voice Messaging Standards

In recognition of the degree of dissatisfaction existing among users because of the inconsistencies in voice messaging applications, attempts were made to adopt some standardization that could be applied to future applications. In the late 1980s, the Voice Messaging User Interface Forum (VMUIF) was established; it was largely composed of representatives from within telecommunications companies in the United States. The VMUIF published (1990) a document of consensus guidelines that were to guide the user interface design of future voice messaging applications. Some years later, this document formed the basis for the voice messaging user interface standards of both the International Standards Organization (ISO) and the American National Standards Institute (ANSI) (ISO, 1995; ANSI, 1996). These standards described the common elements of touch-tone IVR applications, recommended touch-tone key mappings for various IVR application functions, recommended terminology for use in voice messaging applications, and provided design guidelines for implementing the user interface for various functions of a voice messaging system. Blanchard and Lewis (1999) provided a detailed discussion of the content of these standards and of the technical developments that occurred after the standards were published.

Interactive Voice Response User Interface Standard

Introduction

Interactive voice response (IVR) systems were one of the first speech technology–based telephony applications to be widely deployed in the United States. In the first IVR systems, the customer employed touch-tone-based input, and the system provided synthetic speech feedback and prompts as output. Such systems are still in wide use today, although automated speech recognition–based IVR systems, in which users respond with speech instead of touch-tone input, have begun to replace the touch-tone-based applications.

One of the first applications to gain wide implementation was voice messaging, which allowed users to manage telephone voice messages. However, this application was quickly augmented with related and much more complex IVR applications designed to provide many types of customer services, including card credit authorization, utilities problem reporting, automatic bill paying, stock quotations, and travel arrangements and travel information, to name a few. The twofold goal of many of these services was to improve customer service while eliminating human customer service representatives, a significant source of costs to businesses.

Industry was quick to see the potential cost-saving aspect of IVR systems, and companies hurried to develop such systems. With the exception of applications developed within the telecommunications industry specifically, little attention was paid to user interface design during application development, and virtually no standardization took place with respect to prompts, assignments of touch-tone keys to various functions, etc. As a result, users never knew what to expect when they encountered an IVR application, and consequently were unable to develop a mental model of IVR applications or to anticipate the responses required to navigate such systems efficiently and effectively.

Voice Messaging Standards

In recognition of the degree of dissatisfaction existing among users because of the inconsistencies in voice messaging applications, attempts were made to adopt some standardization that could be applied to future applications. In the late 1980s, the Voice Messaging User Interface Forum (VMUIF) was established; it was largely composed of representatives from within telecommunications companies in the United States. The VMUIF published (1990) a document of consensus guidelines that were to guide the user interface design of future voice messaging applications. Some years later, this document formed the basis for the voice messaging user interface standards of both the International Standards Organization (ISO) and the American National Standards Institute (ANSI) (ISO, 1995; ANSI, 1996). These standards described the common elements of touch-tone IVR applications, recommended touch-tone key mappings for various IVR application functions, recommended terminology for use in voice messaging applications, and provided design guidelines for implementing the user interface for various functions of a voice messaging system. Blanchard and Lewis (1999) provided a detailed discussion of the content of these standards and of the technical developments that occurred after the standards were published.

Interactive Voice Response User Interface Standard

Although these standards no doubt had the desired effect of increasing the degree of standardization in voice messaging user interface designs, voice

messaging was already becoming simply one of many applications of IVR technology. Because all voice messaging systems are fundamentally similar, it was possible to standardize the key mappings and even the functionality of such systems. This was not the case for other IVR applications. Nevertheless, developers of IVR applications needed guidance about recommended user interface design principles, because most developers had little human factors knowledge or expertise in-house to guide their user interface design activities. As early as 1992, the development of a more general IVR design guidelines document was recommended (Gardner-Bonneau, 1992). It was not until 1996, however, that the development of such a document was initiated.

In that year, a section originally titled 'Voice input/output and telephony' was added to a standards document being developed by the Human Factors and Ergonomics Society HFES-200 standards committee. This document was intended to be the ANSI complement to ISO Standard 9241 ('Ergonomic requirements for work with visual display terminals, parts 10–17'), which dealt with the user interface for office software systems. (Parts 1 through 9 concerned the hardware user interface for visual display terminals.) A small subcommittee of HFES-200 worked on the 'Voice input/output and telephony' section for approximately 2 years, during which most of its content was finalized. Originally envisioned as having four parts (IVR, automated speech recognition, synthetic speech, and nonspeech audio), this section of the standard was eventually limited to IVR only. The completed IVR section lay dormant for some months, awaiting completion of other sections of the standard.

Between 1998 and 2000, several organizations reviewed the IVR section draft, and one in particular – the Alliance for Telecommunications Industry Solutions (ATIS) IVR Forum – provided feedback that led to significant changes in the draft section. The IVR Forum has as a major goal the development of guidance to help make telecommunications services accessible to people with disabilities, as mandated by Section 255 of the Telecommunications Act of 1996.

The advent of IVR systems, generally speaking, had served some people with disabilities well – specifically, those who were blind. IVR systems enabled blind users to bank, pay bills, and shop by phone and to easily benefit from many other types of customer service that had been problematic via other visually oriented interfaces. However, the very aspect that made IVR systems a godsend for the blind made them virtually inaccessible for people who were deaf or who had hearing impairments. Particularly affected were deaf consumers who needed to access such applications using a text telephone (TTY) or a telecommunications device for the deaf (TDD). Many IVR applications were not available to TTY users (a situation that has since changed), and no attention has been paid to the special user interface requirements of TTY users. Although there were some who failed to understand why a TTY user would want to use an IVR application in the first place, it needs to be said that for many companies in the United States, IVR systems had *replaced* other, comparable forms of customer service, so sometimes an IVR was the only way a deaf user could obtain services on a par with a hearing person.

The HFES-200 document section 'Voice input/output and telephony' – now titled 'Interactive voice response (IVR) and telephony' – had been drafted without any consideration of accessibility issues, but the interest and involvement of the IVR Forum enabled accessibility provisions to be added to the draft in 2000 and 2001. The final version of this section of the standard included general guidelines for IVR user interface design, but has a special designator for those guidelines especially important for accessibility, and includes a set of specific guidelines for the design of IVR user interfaces when TTYs are used.

Some of the specific accessibility-related provisions of the IVR section of the document include the following:

1. TTY users should be informed by the IVR application about the acceptable forms of input (dual-tone multiple frequency [DTMF] – e.g., touch-tone, Baudot [i.e., TTY input], or both).
2. Usability testing should be conducted to determine the appropriate values for IVR elements such as time-outs, structuring of prompts, and text messages used for feedback via a TTY.
3. In the case of delays, TTY users should be provided with appropriate feedback regarding the delay, just as non-TTY users should be.
4. TTY messages should be designed according to the structure and form to which TTY users are accustomed, which differs from that of non–TTY users.
5. Attention must be paid to the quality of audio in prompts to accommodate users who have speech impairments and may have difficulty understanding prompts in an audio-degraded system.
6. To accommodate people with cognitive disabilities and elderly users, IVRs should allow users to replay prompts and announcements in their entirety and to replay portions of announcements and prompts that are especially long and detailed.

Future Directions in User Interface Standards

The HFES-200 Committee in 2000 made the decision to publish and ballot individual sections of the HFES-200 document, rather than wait for all sections to be completed prior to publication. The committee has since published several sections of the HFES-200 document, using the ANSI Draft Standard for Trial Use (DSTU) mechanism. This mechanism allows a draft standard to be placed in use for a period of 6 months, after which it must be balloted for acceptance as an American National Standard. The IVR section is one of the documents that are now available as a DSTU (HFES 200.4, October 2003) and was due to be balloted in late 2004 for acceptance as an American National Standard. At present, there is no international counterpart to this document.

Although the HFES 200.4 DSTU covers touch-tone-based IVR systems, generally it addresses only minimally the speech recognition–enabled IVR systems that are becoming increasingly more common – and this applies to its provisions for making these systems accessible to users with disabilities. Having learned some lessons from the history of touch-tone-based IVR systems, developers of speech-enabled IVR systems have shown some interest in avoiding the past user interface design mistakes that caused touch-tone-based IVRs, although ubiquitous, to be despised by users in many cases. Organizations like the Applied Voice Input/Output Society (AVIOS) have advocated for the development of guidance for the design of speech recognition–enabled IVR interfaces, and near the end of the 1990s, AVIOS briefly supported the formation of a telephone speech standards committee for this purpose (see Gardner-Bonneau, 1999). However, no standard for speech recognition–enabled IVR user interface design has been published yet, although several recent books (Balentine and Morgan, 2002; Cohen *et al*., 2004; Kotelli, 2003) address this topic.

Voice-Over

J Díaz-Cintas, University of Roehampton, London, UK
P Orero, Universitat Autònoma de Barcelona, Barcelona, Spain

The OED (Brown, 1993: 3596) defines voice-over as "narration spoken by an unseen narrator in a film or a television program; the unseen person providing the voice," whereas Webster's online gives us the following definition: "the voice of an unseen narrator speaking (as in a motion picture or television commercial) b: the voice of a visible character (as in a motion picture) expressing unspoken thoughts." In both instances, the underlying approach used to define the term belongs clearly to the realm of Media and Film Studies rather than Translation Studies, as they do not imply any translating activity and no mention of language transfer is made. The English term has been arbitrarily borrowed and adapted by other languages and by Audiovisual Translation Studies scholars who use it in a rather different way, transcending the technical side and incorporating a translation dimension. This dual use of the sameterm with two clearly different meanings is responsible for some terminological confusion.

Very few efforts have traditionally been channeled into the study of this translation mode, a situation that mirrors the lack of interest shown by academics in the more general area of Audiovisual Translation (AVT). The relatively recent boom in AVT has generated much research activity in the field although centering mainly on its two most popular modes of transfer, subtitling and dubbing, bypassing somehow other techniques such as voice-over, surtitling, narration, interpreting, and commentary. It is revealing that no separate entry on voice-over can be found in academic dictionaries and encyclopedias of Translation Studies, having being systematically classified as a subcategory under the umbrella terms of dubbing and revoicing (Shuttleworth and Cowie, 1997: 45; Baker, 1998: 75). In these pages, voice-over is understood as one of the distinct and independent translation modes applied when translating audiovisual programs (for a detailed taxonomy, see Gambier, 1994, 1995, who distinguishes up to 10 different modes).

Another inaccuracy that stems from the two previous dictionary entries is the fact that voice-over is not restricted to motion pictures or the television alone and it is actually much used in radio programs, for instance, on the BBC World Service. Hence, the umbrella term Screen Translation would seem inappropriate in this case as it only applies to translation done for media that are received through a screen. A wider term such as Audiovisual Translation, encompassing all media translation modes, might seem better for this type of activity.

From a Translation Studies perspective, voice-over can be defined as a technique in which a voice offering a translation in a given target language (TL) is heard simultaneously on top of the source language (SL) voice. As far as the soundtrack of the original program is concerned, the volume is reduced to a low level that can still be heard in the background when the translation is being read. It is common practice to allow the viewer to hear the original speech in the foreign language for a few seconds at the onset of the speech and to reduce subsequently the volume of the original so that the translated speech can be inserted. The translation usually finishes several seconds before the foreign language speech does, the sound of the original is raised again to a normal volume and the viewer can hear once more the original speech.

Unlike subtitling, in which there is a shift of medium from an oral discourse in a SL into a written text in a TL that normally appears at the bottom of the screen, voice-over remains in the oral medium in the same way as dubbing. Although there is a certain degree of audio synchrony in the delivery of the original and the translated text – the narrator's voice being heard over the on-screen speaker's voice – one of the main differences with dubbing is that voice-over does not make any attempt to recreate the illusion of lip synchronization. Whereas dubbing pretends that the people on screen speak the same language as the viewer, voice-over is a reminder of the difference and the need for translation. The viewer is constantly aware through the auditory channel of the presence of a foreign language, making voice-over, as well as subtitling, a prime example of what in House's terminology (1981) will be an overt translation, i.e., the program is always presented and perceived as a translation.

There are primarily two professionals involved in this technique: the translator and the voice-over narrator or artist. The former deals with the linguistic transposition from a language into another, whereas the latter is in charge of reading the text in the target language. One of the reasons for this distinction is that more often than not, translators would not possess the desired voice quality and voice artists would not be qualified linguists. The implications of this split have been discussed in detail by Allouba (1992), who raises some thorny issues: the inappropriate mutilation of parts of the translated text, the rightful owner of the copyright and the (in)visibility of the translator.

For commentators such as Luyken *et al.* (1991: 80) the cohabitation of two languages is regarded as a positive factor, as it "contributes to the sense of authenticity in the translation and prevents a degree of mistrust from developing," an opinion that is also shared by Pönniö (1995: 304) for whom voice-over is the ideal translation solution if one wants to give an idea of the interlocutor's tone and way of speaking. Nevertheless, one should be fully aware that this is nothing but an illusion and, as Franco (2001: 290) points out, "the type of delivery we hear in voice-over translation is an important strategic way of reassuring viewers that what they are being told in their own language is what is being said in the original language, although it is known that what they will be listening to is in fact only a *representation* of the original discourse." Although in most countries the standard language variation is used in the translation irrespective of the lexical and paralinguistic characteristics of the SL speech, this drive to promote and foreground the sense of authenticity has given raise to new, bold approaches to voice-over. The change in attitude that has taken place toward the use of voice-over in television is best exemplified in the United Kingdom, and more particularly in the way it is done by the BBC. Thus, where the traditional practice "was to use sedately delivered Received Standard Pronunciation, [. . .], it is now the custom, out of deference to the Other, to use English with the appropriate foreign accent" (Fawcett, 1996: 76). This means that if the person on screen speaks Spanish, the voice-over narrator will read the translation in English with a clear foreign accent, showing the characteristic inflexions that are associated with a Hispanic person speaking English. However, we would argue that this approach is far from being unequivocal and lends itself to debate, as it could also be interpreted as a sign of the inability of foreign people to speak English correctly.

Like subtitling, voice-over has considerable advantages over dubbing in terms of costs. It is technically less complex and demanding since there is no need to adapt the translation to fit the movement of the lips, which has led some authors to state that voice-over does not pose any demands for synchrony (Lambert and Delabastita, 1996; Grigaravičiūte and Gottlieb, 1999), and the only requirement is that the length of the translation is relatively similar to that of the original speech. The apparent lack of media constraints has prompted some scholars to describe it as the easiest and most faithful of AVT modes (Díaz Cintas, 1997: 112; Grigaravičiūte and Gottlieb, 1999: 43). However, the fact that the limitations imposed by the audiovisual media are less stringent in voice-over than in subtitling or dubbing does not mean that they do not exist. Given that the translation starts a few seconds after the original and finishes a bit earlier, there tends to be a demand for lexical reduction in the translation so that the oral delivery does not sound rushed and unnatural when recorded, although voice-overs do admit considerable variation in respect of this type of synchrony. Besides time constraints, and given that we are dealing with a polysemiotic program, the translation will also have to pay attention to any possible linkage between text and image in the original. So, when the SL enunciation is supported by visual images, the translation will have to resort to solutions that, as far as possible, also recreate the link between the two dimensions at the same point in the program. From a technical dimension, the translated text has a time code – TCR – that must be followed in order to keep synchrony with the images. Lack of synchrony in this respect can lead to a negative perception on the part of the viewers.

The oral performance dimension is also simplified as the TL voices do not need to resemble those of the original program and the voice-over speaker – revoicer – does not need to have trained as an actor. The recording is usually carried out by one, or possibly two people – for male and female voices – rather than by several dubbing actors, reducing the labor costs considerably.

The other additional advantage of voice-over is that the amount of time it requires to be completed is far less than for dubbing and can therefore be used for the translation of programs in which there is very little time for preparation before it is due to be broadcast or sent back to the client.

Given its particular nature, voice-over has been traditionally favored in the audiovisual media to translate programs belonging to nonfictional genres, in order to account primarily for an interview answer or series of answers from an interviewee that speaks a different language to the TL audience. Documentaries, current affairs, news and political debates are translated in this way. In countries such as Spain, voice-over is a more common mode of AVT than subtitling, and it is the leading mode when people are interviewed on TV programs, from news and sports to gossip and even reality shows. When foreign Presidents or Prime Ministers have something to say in current affairs, it reaches the Spanish audience through voice-over. For authors such as Kilborn (1993: 648), this transfer mode is "particularly well suited as a method for the rendering of speeches by foreign politicians," so much so that "many in the audience would now deem it wholly inappropriate if any other mode were used."

In addition to interviews, voice-over is also used to translate films and other programs in countries like Belarus, Estonia, Latvia, Lithuania, and Poland. Depending on resources, one or several actors narrate the translation while the original voices are heard as well. There tends to be a greater flexibility in the way the translation is inserted on top of the original language, without the need to leave the original running for a few seconds before hearing the TL text. This type of voice-over is probably closer to what Hendrickx (1984) coined 'partial dubbing.'

Some scholars have classified voice-over as simultaneous interpreting (Gambier, 1994: 276). In our opinion, this approach adds to the confusion surrounding the term, implying that voice-over is used in live performance. However, there are good grounds for distinguishing between the two activities. Simultaneous interpreting of audiovisual programs takes place at the same time as the SL speech and is done live by an interpreter. Translation for voice-over, on the contrary, is done and recorded prior to the broadcasting of the program. The limits between the two modes can be blurred as in the case of news items that arrive shortly before transmission time and are simultaneously interpreted and recorded just in time to be broadcast. Kaufmann, whose many years of experience as an interpreter give her a certain authority, rejects this comparison completely. She makes a clear distinction between modes used in live broadcasting, *l'interprétation in situ*, that is, the simultaneous or consecutive interpreting of live debates and interviews (1995: 436), and modes used in programs recorded prior to broadcasting, *l'adaptation en aval*, that is, the subtitling, dubbing and voice-over of a program into a foreign language (1995: 438).

To conclude, it may be said that the prevailing terminological ambiguity surrounding the term voice-over reflects the scarce interaction between scholars and practitioners. Most important, the prevailing discourse on voice-over reveals that the actual conflict is not so much about terminology but about the object of study itself. That is, it seems that the status of voice-over as a mode of transfer *per se* has been neglected, mainly because it always appears as a technique or a subcategory associated with other well-known types of audiovisual translation.

Volney, Constantin-François Chasseboeuf, Comte de (1757–1820)

V Raby, Université de Reims-Champagne-Ardenne, Reims, France

© 2006 Elsevier Ltd. All rights reserved.

Volney was born on February 3, 1757, in Craon, France, and died on April 25, 1820, in Paris. Son of an attorney, he studied at the Oratorian College in Angers, where he started learning Hebrew. In 1775, he went to Paris to read law but studied medicine and was a member of the baron d'Holbach circle in Auteuil. Beginning in 1780, he studied Arabic at the College de France with Leroux des Hauteraies. In 1785, he invented his pen-name, Volney, which is the contraction of VOL (from Voltaire) and NEY (from Ferney, Voltaire's residence). His first travels to the Near East countries afforded him close observations of geographical, historical, sociological, and ethnographical differences, collected in *Voyage en Egypte et en Syrie* (Volney, 1787). In 1790, he was elected a representative of the Tiers-Etat, became secretary to the Assemblée, and was promoted to director of agriculture and commerce for Corsica (*Précis de l'état de la Corse*, 1793). *Les Ruines,* published in 1791, brought him high repute. After being imprisoned and forced into exile during the Terror, he was appointed to the Ministry of Foreign Affairs in 1794, in charge of the Near East countries. In the second year of the Republic, he was employed as a teacher of history at the Ecole Normale and developed methods of ethnolinguistic investigation. From 1795 to 1798, he traveled to America and studied the Miami language. Back in France, he was elected to the 'Analysis of sensations and ideas' section of the Institut de France. Like several Ideologues, he supported Napoleon Bonaparte and participated in the coup d'état of Brumaire 18. He became a senator but was soon deposed and joined the opponents to the Empire. Volney was a member of the Société des Observateurs de l'Homme and the Société Asiatique de Calcutta, founded in 1783, and became cofounder of the Académie Celtique in 1804. He was made a peer of the kingdom by Louis XVIII. From these years on, his work was devoted to linguistics and ancient history. In his will, he founded the Prix Volney to support the transcription of Near Eastern languages into a phonetic alphabet. In 1842, it became a prize for work in comparative linguistics.

Volney's most famous contribution to linguistics is the *Discours sur l'étude philosophique des langues* (1819). In this essay on the history of linguistic descriptions, Volney explained his comparative method and maintained the thesis of polygenesis. Drawing attention to linguistic discrepancies, considered as cultural facts, he questioned the universalism of the Ideologues and the principles of general grammar. His works on the unification of alphabets and the teaching of Near Eastern languages had many followers. In addition to his effort at planning for collecting grammars and dictionaries, he contributed to the elaboration of modern ethnographic studies and indirectly to the development of comparative linguistics.

Voloshinov, Valentin Nikolaevich (1884/5)

S O'Neill, University of Oklahoma, Norman, OK, USA

© 2006 Elsevier Ltd. All rights reserved.

Valentin Nikolaevich Voloshinov was born in Saint Petersburg, Russia, on June 30, 1895. Though he originally set out to study law, entering Saint Petersburg University in 1913, material circumstances forced him to leave in 1917, before finishing his degree. For the next several years, Voloshinov held a series of teaching stints, serving as a piano instructor for the People's Education Department, for instance, before meeting up with fellow teachers Bakhtin and Medvedev, who were all working in Vitebsk in 1920. The three intellectuals stayed in close contact throughout the 1920s, engaging in lively discussions about language, politics, philosophy, and literature, and forming what is today known as the Bakhtin Circle.

Determined to continue his training as a linguist, Voloshinov returned to his native Saint Petersburg (then renamed Petrograd), where he completed his studies in ethnology and linguistics, finishing his university degree in 1924. The following year, he accepted a position as a research assistant at Saint Petersburg University, in the newly formed Institute for the Comparative History of the Literatures and Languages of the West and East, where he continued as a postgraduate student in 1926, later becoming a research fellow after completing his studies in 1929. Starting in 1932, Voloshinov taught sociology and art at the Herzen Pedagogical Institute, a position he kept until 1934, when poor health forced him to end his professional life. Voloshinov succumbed to the ravages of tuberculosis in 1936, ending a brief but brilliant career that has only recently gained public recognition.

Voloshinov is best known for his sophisticated work on language ideology, a concept he initially drew from Marxist philosophy, with its strong focus on the political ramifications of public consciousness. As Voloshinov came to argue in his seminal work, *Marxism and the philosophy of language* (1929), public discourses are constructed in verbal encounters, in which speakers negotiate worldview through dialogic exchanges, often defending or even countering the dominant ideologies expressed elsewhere in a society. Of course, the whole framework is reminiscent of the dialogic approach to language that Voloshinov's friend, Bakhtin, articulated. For this reason, many scholars are inclined to attribute the writings signed by Voloshinov and published under his name solely to Bakhtin. The issue of authorship remains open, though many now entertain the possibility that the influence was mutual. In this article, the works published under Voloshinov's name are treated as his alone.

Deeply dissatisfied with the linguistics of his day, Voloshinov sought to develop a new school rooted in social interaction rather than in abstract structural characteristics, such as phonetics, lexicon, and grammar, which were increasingly being studied for their own sake. Voloshinov argued that linguists had adopted an inappropriate methodology derived from the study of dead languages, in which the utterance was, of necessity, removed from its original social setting as an isolated, monologic byproduct. Yet in a living language the utterance is central to the construction of meaning, which derives as much from the social context as it does from structural traits, such as word order or grammatical categories.

For Voloshinov, the meaning of an utterance is always based on a specific 'theme,' or a common stock of assumptions shared by participants, one that is generally rooted in the unrepeatable circumstances of the encounter. From this perspective, a word or grammatical concept takes on subtle new shades of meaning every time it is uttered. Consider the use of the pronoun 'we' in the framing of the American constitution, where the reference once excluded both women and slaves, who were systematically barred from participating in the government for

Valentin Nikolaevich Voloshinov was born in Saint Petersburg, Russia, on June 30, 1895. Though he originally set out to study law, entering Saint Petersburg University in 1913, material circumstances forced him to leave in 1917, before finishing his degree. For the next several years, Voloshinov held a series of teaching stints, serving as a piano instructor for the People's Education Department, for instance, before meeting up with fellow teachers Bakhtin and Medvedev, who were all working in Vitebsk in 1920. The three intellectuals stayed in close contact throughout the 1920s, engaging in lively discussions about language, politics, philosophy, and literature, and forming what is today known as the Bakhtin Circle.

Determined to continue his training as a linguist, Voloshinov returned to his native Saint Petersburg (then renamed Petrograd), where he completed his studies in ethnology and linguistics, finishing his university degree in 1924. The following year, he accepted a position as a research assistant at Saint Petersburg University, in the newly formed Institute for the Comparative History of the Literatures and Languages of the West and East, where he continued as a postgraduate student in 1926, later becoming a research fellow after completing his studies in 1929. Starting in 1932, Voloshinov taught sociology and art at the Herzen Pedagogical Institute, a position he kept until 1934, when poor health forced him to end his professional life. Voloshinov succumbed to the ravages of tuberculosis in 1936, ending a brief but brilliant career that has only recently gained public recognition.

Voloshinov is best known for his sophisticated work on language ideology, a concept he initially drew from Marxist philosophy, with its strong focus on the political ramifications of public consciousness. As Voloshinov came to argue in his seminal work, *Marxism and the philosophy of language* (1929), public discourses are constructed in verbal encounters, in which speakers negotiate worldview through dialogic exchanges, often defending or even countering the dominant ideologies expressed elsewhere in a society. Of course, the whole framework is reminiscent of the dialogic approach to language that Voloshinov's friend, Bakhtin, articulated. For this reason, many scholars are inclined to attribute the writings signed by Voloshinov and published under his name solely to Bakhtin. The issue of authorship remains open, though many now entertain the possibility that the influence was mutual. In this article, the works published under Voloshinov's name are treated as his alone.

Deeply dissatisfied with the linguistics of his day, Voloshinov sought to develop a new school rooted in social interaction rather than in abstract structural characteristics, such as phonetics, lexicon, and grammar, which were increasingly being studied for their own sake. Voloshinov argued that linguists had adopted an inappropriate methodology derived from the study of dead languages, in which the utterance was, of necessity, removed from its original social setting as an isolated, monologic byproduct. Yet in a living language the utterance is central to the construction of meaning, which derives as much from the social context as it does from structural traits, such as word order or grammatical categories.

For Voloshinov, the meaning of an utterance is always based on a specific 'theme,' or a common stock of assumptions shared by participants, one that is generally rooted in the unrepeatable circumstances of the encounter. From this perspective, a word or grammatical concept takes on subtle new shades of meaning every time it is uttered. Consider the use of the pronoun 'we' in the framing of the American constitution, where the reference once excluded both women and slaves, who were systematically barred from participating in the government for

some time to come. Or consider the racial use of the color terms 'black' and 'white' before the civil rights movement of the 1960s. Ordinary words can propagate powerful social ideologies for specific groups in specific times. Yet Voloshinov also maintained that linguistic concepts retain a core ideological neutality and potential multivalence, allowing them to potentially convey any ideology or even mean different things to different groups at different times. Hence, the expression 'we the people' no longer excludes women, though it did in early America. In actual use, Voloshinov argued linguistic concepts always carry an evaluative, ideologically charged sense – meaning that they always convey specific perspectives, often with strong political overtones.

Where Saussurean linguists posited an idealized speaker–hearer with a perfect command of relatively homogeneous grammar and vocabulary, Voloshinov argued that meaning is always changing through use, and speakers differ profoundly in their knowledge, stylistic preferences, or deployment of grammatical rules. Where Saussurean linguists represented communication with arrows passing from an active speaker to a passive addressee, who merely decodes the speech by relying on the conventional meanings of linguistic concepts, Voloshinov argued that communication was in fact a two-way street or 'double-sided act,' in which the receiver also plays an active role in shaping meaning, anticipating contemporary speech act theory. For Voloshinov, the listener also plays a role in shaping the exchange, whose outcome neither party ever fully anticipates. Finally, where the Saussurean model of the invariant linguistic sign relegated the messy issue of change to the diachronic realm, where its source still remained mysterious, Voloshinov regarded change as a byproduct of dialogue, or the constant negotiation of per-spective in actual language use, where structure and meaning are always undergoing subtle revision.

Because his new school of linguistics was based on the ideologically charged utterance, Voloshinov devoted a whole section of *Marxism and the philosophy of language* to problems of 'reported speech.' For, in actual pratice, speakers spend a great deal of time quoting or repeating the words of other speakers. Also, if the linguist analyzes speech, the discipline had better develop a methodology for accurately reporting the utterance, without ignoring the author's role in shaping meaning assigned to speakers. One approach is to maintain sharp boundaries between authorial and reported speech, clearly separating the two voices with quotation marks or subordinate clauses, for instance. In contrast to this painstaking 'linear' method, Voloshinov notes the existence of the 'pictorial' approach, in which the author takes the liberty of interspersing the reported speech with commentaries and replies, as in literature. Another tendency is to capture the content, if not the style, a approach Voloshinov dubbed the 'referent analyzing' approach, as opposed to the contrasting 'texture analyzing' approach, in which the author strives to capture the tone and feel of the reported speech.

This article is reproduced from the previous edition, volume 9, pp. 4953–4954, © 1994, Elsevier Ltd.

Vossler, one of the most influential (and controversial) Romance scholars of his epoch, not only in Germany, was born on September 6, 1872 at Hohenheim (near Stuttgart). He studied German and Romance Philology at Tübingen, Strasbourg, and Geneva. In 1895 he went to Rome, turning his attention mainly to Romance languages and literatures. In 1899, he made the acquaintance of Benedetto Croce (*see* **Croce, Benedetto (1866-1952)**), an acquaintance which subsequently grew into a lifelong friendship. He adopted Croce's aesthetic concept of language and later became the founder of the so-called 'idealistic school' of philology. For more than 10 years he was lecturer in Italian at the University of Heidelberg. During the short period in which he held the chair of Romance Philology at the University of Würzburg (1909–1911), his new professional duties drew his attention to French language and literature. In 1911 he was offered the chair of Romance Philology at the University of Munich, where he remained for the rest of his life.

Vossler was a fervent German patriot, yet anything but a nationalist. Disappointed by political developments in Italy during World War I, horrified by the rise of Fascism in Italy and Nazism in his own country, hurt by the uncompromisingly anti-German attitude adopted by France, a country to which he felt attached by a kind of love-hate relationship, he concentrated his efforts in his later years almost entirely on Spanish language and literature. In 1938 the Nazi administration of his alma mater obliged him to relinquish his chair prematurely. In 1946 he was entrusted with the rectorship of the University of Munich by the American Military Government, an office which he had already held in 1926. He died in Munich on May 18, 1949.

Vossler began his academic career as a traditional philologist. However, after the 'idealistic turn' in his intellectual biography he became convinced that the language of a people reveals itself in its literature. Thus, according to his view, the 'natural way' of investigation is to start from language seen in its totality, that is, as artistic creation, and to proceed from there to individual linguistic phenomena such as forms and sounds, and not vice versa. The really important and interesting part of language is due to individual creation, its collective and systematic aspect being nothing other than a result of human inertia. Grammar has to be studied as a manifestation of 'frozen collective style.'

Vossler declared war on 'positivistic' philology in his pamphlet *Positivismus und Idealismus in der Sprachwissenschaft* (1904); he attempted to apply his theoretical principles to a concrete subject in his book on French language and culture (Vossler, 1913), but this only brought him scorn and derision from his less 'idealistic' colleagues. In *Geist und Kultur in der Sprache* (Vossler, 1925), a collection of some important theoretical essays, he advanced his opinions on the mutual relationship between language and culture in a more circumspect form. The majority of his numerous publications are of literary rather than linguistic interest.

Vowel Shifts and Mergers

E R Thomas, North Carolina State University, Raleigh, NC, USA

© 2006 Elsevier Ltd. All rights reserved.

Overview

Quantitative approaches to language variation began with studies of shifts and mergers of vowels, and vowel changes have maintained a central position in variationist linguistics. Labov's (1963) study of Martha's Vineyard in Massachusetts was a study of the shifting of the vowels of PRICE and MOUTH. The majority of the variables in his study of the Lower East Side of Manhattan, New York, involved vowel shifts (Labov, 1966). On the other side of the Atlantic, quantitative sociolinguistics started with Trudgill's (1974) studies of Norwich, England, which itself studied vocalic variation, such as the merger of *toe* and *tow* and shifting of the *toe* class. In other countries as well, quantitative sociolinguistics has often taken root with studies that included vowel shifting or merger as variables, e.g., Horvath (1985) in Australia.

This survey focuses on variationist, or quantitative sociolinguistic, approaches. Nevertheless, it builds on other approaches to vowel shifting and merger from other branches of linguistics. Most important are those from historical linguistics (e.g., Martinet, 1952) and dialect geography (e.g., Moulton, 1962). Much recent work in sound shifting, such as Labov (1991, 1994), Thomas (2001), and Labov *et al.* (in press), also relies heavily on methods originally developed in phonetics.

A large fraction of variationist work on vowel shifting and vowel mergers have concerned dialects of English. There are several reasons for this bias. One reason is that continental European scholars have tended to be preoccupied with other important issues, such as language contact and the leveling of traditional dialects, and have maintained a greater interest in dialect geography than anglophone scholars. Another reason is that the small vowel systems found in many languages, such as the five-vowel system of Spanish, tend to be rather stable and, thus, provide little information on vowel shifting. Meanwhile, English, with its complicated, unstable vowel system, has proved exceptionally fertile for studies of vowel shifting. A third reason is that sociolinguistic research on non-European languages, with a few exceptions such as Japanese, Arabic, and some languages of India, has been quite limited.

Names of vowel classes in English used in this article follow the system devised by Wells (1982), in which keywords, such as KIT or THOUGHT, represent the vowel contained in them. This convention circumvents issues of what constitutes a phoneme (or even if phonemes exist), as well as British/American differences in conventional names of vowel classes. For other languages, conventionally recognized symbols for phonemes are employed.

Vowel Shifting

The study of vowel shifting traditionally lay within the realm of historical linguistics, though dialectology added useful insights as well. In recent years, however, sociolinguistics has become the dominant center of research on vowel shifting, with important contributions from phonetics and phonology. Sociolinguists, following the lead of William Labov, have developed a set of theories and provided large amounts of data on vowel shifting, particularly in varieties of English. Some issues related to vowel shifting, especially its causes, have spanned the various fields that have investigated it.

A vowel shift occurs when the quality of a vowel phoneme changes over time. For example, the vowel in the English word *seed* was pronounced [eː] before 1500, but during the century or two after 1500 it changed to [iː], at least in many dialects. This particular shift was an example of an unconditioned change, one that affects all phonetic contexts. Vowel shifts may also be conditioned, that is, occurring only in particular phonetic contexts. Examples of conditioned changes are the lowering of /ɛ/ to [æ] in Canadian French, which occurs only word-finally, as in *lait* [læ] 'ugly' (Walker, 1984) and the similar lowering of /ɛ/ to [æ] in Swedish and some dialects of Norwegian, which occurs only before /r/, as in *är* [æʈ] 'am, is, are'. Conditioning of vowel shifts is quite often due to assimilation to a consonant that conditions the shift. For instance, fronting of GOAT and GOOSE in English is blocked when /l/ follows the vowel, as in *cold* and *cool*. The reason is that syllable-coda /l/ is velar in English and coarticulation with the velar /l/ keeps the vowel velar, preventing it from fronting (i.e., palatalizing).

Studies of vowel shifting can provide important evidence for wider linguistic issues. For example, the Neogrammarian controversy was reviewed by Labov (1981). The dispute involves whether sound change is exceptionless and conditioned only by phonetic factors – the Neogrammarian hypothesis first advocated by Hermann Osthoff and Karl Brugmann – or occurs word by word – lexical diffusion, advocated most notably by William S.-Y. Wang. By examining evidence from sociolinguistic studies, Labov found

that many cases that had previously been ascribed to lexical diffusion were actually instances of social variation in which speakers used both competing variants. At the same time, however, he found that some kinds of changes, such as those involving vowel length, often do behave in lexically specific ways.

Causes of Vowel Shifts

Considerable research has focused on vowel shifts that are internally motivated, that is, not due to influence from a substrate language or from prestige-related hypercorrection. One old explanation for vowel shifts and other sound changes, economy of effort, has been applied productively to conditioned changes that are due to assimilation. Economy of effort, also called the principle of least effort, states that sound changes occur in order to minimize energy expended in articulation. That is, in a word such as *cool*, it is easier to maintain the vowel in a backed (velar) position before the velar /l/ by simply holding the tongue in the same position than it is to move the tongue so that the constriction forms first in the palatal region and then rapidly shifts to the velar region. Assimilatory shifts are usually conditioned, as in the example just given, but they can also be unconditioned in many cases of monophthongization of diphthongs. In these cases, the nucleus and the glide of the diphthong become assimilated to each other. For example, Old Latin /oi/ changed to /uː/ in Classical Latin, as in *oinos* 'one'> *ūnus*; /uː/ was, in a sense, "halfway" between [o] and [i] because it preserved the backness and rounding of [o] while maintaining the height of [i]. (/oi/ was preserved in a few words, e.g., *foetidus* 'stinky', but perhaps mainly as a spelling convention.) Similarly, Classical Latin /ai/ (spelled *ae* or *æ*) and /au/ became Vulgar Latin /ɛː/ and /ɔː/, respectively, sounds that are "halfway" between their former nuclei and glides. Monophthongization may also involve one-way assimilation, as in the shift of Proto-Germanic */ai/ to Old English /ɑː/, for example, **stainaz* 'stone' > *stān*, or the similar shift of the PRICE class in some or all phonetic contexts to [aː] in the American South.

Nevertheless, economy of effort has three primary weaknesses as an explanation for vowel change. The first is that it is counteracted by the need for clarity in speech. While the desire for economy may induce speakers to expend less effort in articulation, thereby producing less movement of articulators and more overlapping of articulatory gestures, the need for clarity has the opposite effect, leading to a greater effort in utterances, with more movement of articulators and somewhat less overlapping of gestures. Up to a point, greater articulatory effort makes it easier for addressees to understand the message, which is normally an aim of any speaker. As a result, economy of effort leads to far fewer vowel shifts than might be expected. A second weakness is that it fails to explain why anticipatory coarticulation leads to more vowel shifts than perseveratory coarticulation: that is, vowels exhibit shifts conditioned by segments that follow them more often than by segments that precede them. This issue is perhaps best left to experimental phonetics and neurolinguistics. The third, and widest-ranging, weakness is that a large number of vowel shifts are left unexplained. Among these unexplained shifts is the bulk of unconditioned vowel changes.

Another explanation besides economy of effort, the notion of maximal differentiation – that vowels tend to be situated in the vowel envelope so that they are spaced as far from each other as possible – has shed light on many unconditioned vowel shifts and has appeared in varying incarnations in several branches of linguistics. Martinet (1952) discussed the functionalist-influenced slot-filling approach, in which there were spaces for, e.g., a high back rounded vowel, a mid back rounded vowel, etc., and each of those slots might or might not be filled in a particular language. This construct was commonly assumed by historical linguists at the time and, in some form, precedes Functionalism, going back at least to Jakob Grimm. Martinet modified it by advocating the notion of a margin of security between phonemes, a space between each phoneme in which tokens ordinarily do not occur. Later sociolinguistic and phonetic findings have complicated the picture considerably with regard to the margin of security. It has been demonstrated repeatedly, by means of first formant (F_1)/ second formant (F_2) plots, that no empty space between phonemes is necessary and, in fact, that overlap is common. When segmental and prosodic contexts are taken into account, the picture clears up considerably, and at least a modicum of the margin of security is usually present – though, here again, exceptions are possible. What may be more lasting about Martinet's approach, however, is that he seems to have regarded addressees as highly as speakers in the equation. According to the scheme for which Martinet argued, if one vowel in a chain happened to shift, then the next vowel could afford some slop into the space that the first vowel had vacated. Tokens of the second vowel could be produced in that space and would not create comprehension errors for the addressee, so they could be perpetuated, creating the possibility that the whole "center of gravity," as Martinet put it, of the second vowel could shift. Thus, with both the first vowel and the second vowel mutated, a chain shift would be created.

More evidence that vowels tend to be distributed evenly around the vowel space appeared in Moulton (1962), which showed that variants of /aː/ in Swiss German dialects were related directly to the structure of the rest of the vowel system. The change in emphasis to perception progressed further in phonetic studies of vowel dispersion. Liljencrants and Lindblom (1972) initiated this movement. They surveyed the vowel systems of languages around the world and found that mathematical modeling could predict the configurations of vowel systems based on the number of vowel phonemes, at least for smaller systems. Later studies have refined the method. The notion that vowels are maximally dispersed in the vowel envelope presupposes a primacy for perception because keeping the vowels as far from each other as can be leads to fewer comprehension errors by listeners.

Martinet's ideas laid a foundation for variationist studies of vowel shifting. Variationists have taken the lead in working out some problems with the scheme. As noted above, one problem for Martinet's scheme is that the margin of security that he proposed is not always present. The problem is related to another assumption that Martinet made, that chain shifts are necessarily pull chains, with the vowel at the front of the chain being the first to shift. Other scholars have presented evidence that the head of the chain is not always the first to shift. In such cases, a vowel may encroach on another vowel, with the result that the vowel that is encroached upon later shifts away from the encroacher. A situation of this sort is termed a push chain. Labov (1994) reviews the issue of pull chains vs. push chains, providing evidence for both. A third possibility, which could be hypothesized from the phonetic studies of vowel dispersion, is that chain shifts of vowels could be both pull chains and push chains at the same time. Within a community in which a chain shift of two vowels, B→A→A′, is occurring, it is conceivable that some individuals may have B relatively more shifted than A, with B thus encroaching on the space of A, while other individuals have A relatively more shifted than B, creating a space between A and B. The acoustic data presented by Labov (1994) and other authors tend to be based on analyses of a small number of speakers and thus could easily be somewhat skewed. It is, of course, quite difficult to conduct a comprehensive study of a community that would preclude such skewing.

Martinet was careful to avoid a teleological approach to chain shifting, that is, one in which vowels shifted for a particular purpose – that of making perceptual distinctions among phonemes clearer, for example. However, sociolinguistic studies have revealed teleology of a completely different type in vowel shifting: vowel shifting may serve social purposes. This phenomenon is a pervasive finding in sociolinguistic studies, but its interaction with phonetic factors is not entirely worked out. It appears that language users select variants from among those that phonetic factors promote. The selected variants then can be used to signify various kinds of identity.

The principle of maximal differentiation, like economy of effort, has its limitations. The biggest limitation is that it does not explain the patterns of directionality in vowel shifts that recur across languages. For example, high back vowels become fronted far more often than high front vowels become backed. The most extensive inquiry into these factors thus far has been conducted by William Labov. Labov surveyed known chain shifts of vowels, mostly historical, in order to find recurring patterns in their operation. He found a number of such patterns, which he codified into principles that are listed in slightly different forms in Labov (1991) and Labov (1994). A key feature of his principles is a distinction between peripheral and non-peripheral vowels. Similar distinctions had been made before, but Labov based his classification on acoustic evidence. Peripheral vowels are those that occur along the margins of the vowel envelope in the F_1/F_2 space, while non-peripheral vowels are those that occur away from the margins. In addition, he specified that the principles apply not only to monophthongal nuclei, but also to diphthongal nuclei. The principles, as given in Labov (1994), are:

- Principle I. In chain shifts, long vowels rise.
- Principle II. In chain shifts, short vowels fall.
- Principle IIa. In chain shifts, the nuclei of upgliding diphthongs fall.
- Principle III. In chain shifts, back vowels move to the front. (Or: In chain shifts, tense vowels move to the front along peripheral paths, and lax vowels move to the back along non-peripheral paths.)
- Principle IV, the lower exit principle. In chain shifting, low non-peripheral vowels become peripheral.
- Principle V, the upper exit principle. In chain shifting, the first of two high morae may change peripherality, and the second may become non-peripheral.
- Principle VI, the mid exit principle. In chain shifts, peripheral vowels rising from mid to high position develop inglides.
- Principle VII, the redefinition principle. Peripherality is defined relative to the vowel system as a whole.
- Principle VIII, the unmarking principle. In chain shifts, elements of the marked system are unmarked.

In an earlier version, Labov (1991) had stated the first two principles as "Peripheral nuclei rise" and "Non-peripheral nuclei fall," respectively. Besides the stipulation that the principles applied only in chain shifts, he also specified (1994: 280) that short vowels are consistently non-peripheral, while long monophthongs are usually, though not always, peripheral. The correlation between peripherality and direction of shifting remained, then. The first two rules, in the 1994 formulation, are limited to languages that distinguish long and short vowels or make an analogous distinction, such as the 'tense/lax' opposition of Germanic languages. Labov provided numerous examples of the operation of these rules from languages besides English. For instance, Old High German /iː/ and /uː/ diphthongized according to Principle V and their nuclei fell along the non-peripheral paths according to Principle IIA, leading to Modern German /ai/ and /au/, respectively. Old High German /eː/ and /oː/, meanwhile, rose along the peripheral paths as per Principle I and developed inglides as per Principle VI, giving rise to [iə] and [uə], respectively; the inglides were later smoothed, resulting in Modern German /iː/ and /uː/. Another example is the chain shift of Swedish long back vowels. The long back vowels rose along the back peripheral path, following Principle I: the former /aː/ shifted to /ɑː/, /ɔː/ became the new /oː/, and the old /oː/ became the new /uː/. The former /uː/ fronted to a vowel conventionally denoted as /ʉː/, following Principle III.

In spite of the utility of these principles in explaining vowel shifting patterns, they have not escaped criticism. One of the major difficulties with them is that it is not always clear which vowels are peripheral and which are non-peripheral, and peripherality has not proved quantifiable. Another, probably related, problem is that it is not clear that peripherality is really a causal factor in the shifting patterns associated with it. Labov has never written that peripherality actually is a causal factor, though it seems to be implied in his writings. He certainly does not provide a plausible mechanism for how peripherality could cause shifts. Nevertheless, there is reason to think that peripherality is more of a side effect than a cause and that, perhaps, the real causes should be sought in the slate of articulatory factors that distinguish tense from lax vowels.

Variationist Studies of Vowel Shifting Patterns

A large portion of Labov's evidence came from contemporary chain shifts occurring in English, and these are the shifts that other variationists have studied most intensively. One is a chain shift that had virtually escaped notice until Labov, dubbing it the 'Northern Cities Shift,' drew widespread attention to it. It occurs in a broad area on the U.S. side of the Great Lakes. In this shift, schematicized in Figure 1, the TRAP/BATH vowel becomes raised and broken to [ɛə∼ɛæ]; the LOT vowel is fronted to [a] and nearly to [æ]; the THOUGHT/CLOTH vowel is lowered to [ɒ] and sometimes even unrounded to [ɔ]; the STRUT vowel is backed and sometimes rounded to [ʏɑ]; the DRESS vowel is lowered toward [a] and/or backed to [ɜ]; and the KIT vowel sometimes shows some lowering and/or backing toward /ɛ∼ɨ/. Shifting of the first three vowels is older than that of the last three. In addition, the Northern Cities Shift seems to be considerably more advanced in large metropolitan centers than in nearby rural areas, hence its name.

Figure 1 The Northern Cities Shift.

Labov's most detailed phonetic descriptions of the Northern Cities Shift appear in Labov (1991, 1994) and Labov *et al.* (in press). His work has given rise to a considerable number of other studies on sociolinguistic aspects of this chain shift. The most acclaimed of these studies are those by Penelope Eckert (e.g., Eckert, 1989), who found, based on fieldwork in a suburb of Detroit, that the newer components of the chain shift were more advanced among adolescents who identified with a counterculture ethic.

Opposed to the Northern Cities Shift, according to Labov, is another rotation of vowels that he called the Southern Shift. It involves a number of shifts. The nuclei of the KIT and DRESS vowels are peripheralized and raised, while the nuclei of FLEECE and FACE become non-peripheral and are lowered. The PRICE diphthong either is monophthongized to [aː] or has its nucleus backed, yielding [ɑi∼ɒi], and the CHOICE diphthong may be raised to [oi∼ui]. THOUGHT is raised to [oː] or diphthongized to [ɔo∼ɒɔ]. Finally, GOOSE and GOAT are fronted except before /l/, and they each may show some lowering of their nuclei. The Southern Shift is outlined in Figure 2. The Southern Shift occurs throughout the U.S. South, as well as in the dialects of southern England and in most Southern Hemisphere varieties of English, including Australian, New Zealand, and South African English. There are numerous variations on the Southern Shift across this vast area. In New Zealand, KIT is not peripheralized and raised but instead is centralized to [ə], and DRESS

Figure 2 The Southern Shift.

Figure 3 The Canadian Shift.

and TRAP are raised to [i] and [ɛ], respectively (see Bauer, 1986 and several subsequent studies). Monophthongization of PRICE, at least when it is not followed by a voiceless consonant (as in *prize* and *pry*), is more common than backing of the nucleus in the American South, while the opposite is true in England and the Southern Hemisphere. Upgliding forms of THOUGHT and ingliding forms of DRESS and KIT predominate in the American South, while monophthongal forms of those vowels predominate in England and the Southern Hemisphere. The glide of GOAT may or may not be fronted along with the nucleus.

One component of the Southern Shift has been called the diphthong shift by Wells (1982), who used it largely for describing dialects of England and the Southern Hemisphere. This component is the shifting of FLEECE, FACE, PRICE, and CHOICE to [ii∼əi], [ai∼æi], [ɑi∼ɒi], and [oi∼ui], respectively. Its progress and social status have received considerable attention in England (e.g., Kerswill and Williams, 2000), Australia (e.g., Horvath, 1985), and New Zealand (e.g., Bauer, 1986).

Labov (1991: 34) noted that, despite his earlier assumption that little vowel shifting occurred in dialects with the merger of the LOT and THOUGHT vowels, fronting of GOOSE and GOAT seemed to be widespread in such dialects. Since then, the fronting of those two vowels in merger dialects has been confirmed: see, e.g., the list of studies that have found GOAT-fronting in widely scattered locations in Thomas (2001: 28–29). Labov's own subsequent work has found GOOSE-fronting to be widespread in merger areas and has found GOAT-fronting to be most advanced in the southern part of the Midwest, where the LOT/THOUGHT merger is common (Labov *et al.*, in press). The widespread presence of GOAT- and GOOSE-fronting in areas with the LOT/THOUGHT merger has cast doubt on the notion that the Southern Shift is a unified process, since other aspects of the Southern Shift are not common in merger areas. Instead, the Southern Shift appears to be an amalgam of several independent processes. At any rate, the LOT/THOUGHT merger has not inhibited all vowel shifts. Recent findings have reinforced this conclusion. In a process dubbed the Canadian Shift by Clarke *et al.* (1995), the KIT, DRESS, and TRAP vowels fall in a chain, as shown in Figure 3. Though the Canadian shift is not confined to Canada, it – or, at least, lowering of TRAP – has been found in North America only in areas with the LOT/THOUGHT merger: various parts of Canada, the West Coast of the United States, and central Ohio. Rounding of the merged LOT/THOUGHT vowel, which occurs in Canada, could also be considered part of the Canadian shift and seems to amplify the other parts.

Vowel shifting among ethnic groups has fostered its own set of studies. A number of studies, e.g., Thomas (2001) and Fridland (2003), have investigated the vowels of African Americans. African-Americans generally show, for example, more raising of KIT, DRESS, and TRAP than European Americans from the American South, but less lowering of the nuclei of FACE and FLEECE. The vowel shifting patterns of other ethnic minorities, such as Mexican Americans in the United States or Jamaicans and various Middle Eastern groups in England, are also beginning to attract some attention. Substrate influence may account for vowel shifting in the dialects of many minorities. For example, Bernstein (1993) found that Hispanics in Texas tended to show more backed nuclei of the MOUTH diphthong than Anglos, probably because Spanish allows [au] but not [æu] or [æo]. Similarly, monophthongal realizations of GOAT and FACE are well known as dialectal features of Minnesota and adjacent states, which experienced heavy immigration from Germany and Scandinavia during the 19th century.

The effects of vowel shifts on perception have been studied from different angles. One way is in whether listeners can identify the geographical origin or ethnicity of a speaker based on vowel quality and other variables. Another approach has been to elicit the subjective reactions of listeners to voices with differing vowel quality on such scales as intelligence and friendliness. Yet another design, utilized in different forms by, most notably, Renée van Bezooijen for Dutch (e.g., Bezooijen and Berg, 1999) and William Labov for American English, has been to test for the

intelligibility of dialectal variants to listeners or to test what features (including vowel shifts) listeners access for dialectal identifications. These approaches are reviewed more fully in Thomas (2002).

Mergers and Splits

Mergers

Mergers have attracted more widespread attention from sociolinguists than chain shifts have. One reason is that mergers affect the language structurally because they result in the net loss of a phoneme. Other important reasons are that mergers are often associated with the expansion of certain language varieties at the expense of others – a heavily researched topic in Europe – and that varieties spoken by recent immigrants are prone to mergers.

Mergers may be conditioned or unconditioned. Conditioned mergers are those that occur only in certain phonetic contexts. A well-known example is the merger of the KIT and DRESS vowels before nasals in the English of the American South, which is sometimes called the *pin/pen* merger. In this merger, pairs such as *pin* and *pen* or *him* and *hem* become homophonous, but pairs such as *pit* and *pet* or *hid* and *head* never do.

Unconditioned mergers are those that occur in all phonetic contexts. An example is the LOT/THOUGHT merger, in which vowels formerly pronounced as [ɑ] and [ɒ], respectively, have coalesced in the English of large parts of North America. Examples from other languages include the recent merger of /eː/ and /ɛː/, as in *wegen* /ˈveːgən/ 'because of' and *wägen* /ˈvɛːgən/ 'weigh', in many varieties of German, including the standard dialect; the merger of /e/ and /ɛ/ in Turkish, as in *el* /el/ 'people' and *el* /ɛl/ 'hand', which occurs in most dialects of Turkish and is even reflected in the standard orthography; and the merger in Parisian French of /a/ and /ɑ/, as in *matin* /ˈmatɛ̃/ 'morning' and *mâtin* /ˈmɑtɛ̃/ 'mastiff.'

As Labov (1994) argues, mergers *per se* do not seem to attract much social comment. The same is probably true of phonemic splits. That is, listeners do not comment on whether a speaker distinguishes two sounds. Instead, they comment on the quality of particular phones. For example, Americans notice that southern British speakers have an [ɑː] phone in such words as *last*, *half*, and *can't* rather than the American [æ], but it may not occur to them that Brits show a different vowel in *last*, *half*, and *can't* than in *bad*, *hat*, and *stand*, and, when impersonating British speakers, they may erroneously insert [ɑː] in the latter group of words.

Mergers of vowels are often facilitated by dialect mixture. The LOT/THOUGHT merger in North American English is especially prevalent in the West, an area whose original Anglophone settlers hailed from diverse regions of the East. In England, judging by results from the *Survey of English Dialects*, the *maid/made* and *tow/toe* mergers may have originated in London, which has been a destination of migrants for centuries. One possible way that such mixtures lead to mergers might occur if migrants bring different realizations of vowel classes with them, so that the realization of a vowel class in one dialect coincides with the realization of a different vowel class in another dialect, and some language learners are unable to sort the classes out. In this case, the different realizations may become allophonic variations of the newly merged vowel, which would represent *merger by expansion*, as described by Labov (1994). Merger by expansion simply means that the new vowel class extends over the acoustic space that both of the merged classes had taken up. Another scenario occurs if migrants bring different realizations of vowel classes with them and a realization in one dialect becomes stigmatized, leading speakers of that dialect to transfer words from the sound class with the stigmatized realization to another class without a stigmatized realization. This situation would represent what Labov (1994) called merger by transfer. A third scenario, called merger by approximation, would be applied to a situation in which two vowels shift closer and closer to each other until the distinction between them is lost.

Another factor that facilitates mergers, in this case of conditioned mergers, is vocalization of consonants or other consonantal influence. A variety of mergers of vowels before /l/, making homophones of, e.g., *pool* and *pull* or *feel* and *fill*, have been reported in parts of North America and New Zealand in which /l/ is vocalized. The *pin/pen* merger, in all likelihood, stems from the effects of co-articulatory nasality. Nasality adds nasal formants to the vowel formant pattern, as well as antiresonances, which can sometimes obliterate an oral formant. Both nasal formants and antiresonances make the quality of the vowel more difficult to distinguish. This factor also leads to reduction in the number of contrasting nasal vowels in a language; for example, French has nine or ten oral vowels but only three or four nasal vowels, and Cherokee has five oral vowels but only one nasal vowel.

Mergers are often associated with language shift because substrate influence may eliminate some distinctions. For example, Herold (1997) found that communities in eastern Pennsylvania that showed the LOT/THOUGHT merger were those that had earlier had considerable immigration from eastern Europe. In general, eastern European languages – Slavic and

non-Slavic – have simpler vowel systems than English. Similarly, Bernstein (1993) found that, in Texas, Hispanics were more likely to produce unrounded vowels in *lost* and *walk*, which are symptomatic of the LOT/THOUGHT merger, than either Anglos or African-Americans. Their substrate language, Spanish, lacks a contrast between [ɑ] and [ɔ]. Creolization is especially prone to producing mergers. Some Anglophone creoles, for instance, show a merger of the TRAP and LOT vowels; this merger is not found in any non-creolized Anglophone varieties.

Conversely, immigrant groups may lose contrasts in their original language because of influence from their target language. In Australia, for example, Germans were losing contrasts between front unrounded and front rounded vowels, which Australian English lacks, in their German (Clyne, 1972). The approach of language death may result in wholesale confusion of contrasts in a language, with both mergers and addition of new contrasts through borrowing. Connell (2002) reports such a case for Cambap, a language spoken by fewer than 35 middle-aged and older people in western Cameroon. Cambap formerly had about eight contrasting vowels, but influence from Kwanja, a ten-vowel language in which the Cambap speakers were also fluent, had destabilized the system in Cambap. The remaining speakers showed considerable variation in the incidence of vowel mergers and borrowed vowels in their idiolects.

The encroachment of mergers on insular dialects is a common pattern. An exemplary case is that of Long Island in Newfoundland, as described by Colbourne (1982). In this dialect, reflexes of Middle English /ai/, as in *day* and *maid*, were formerly distinct from the FACE class, so that *maid* and *made* were pronounced differently. The NORTH and FORCE classes were also formerly distinct. However, these distinctions were eroding rapidly and were found mainly in the speech of older males, especially those with less education. In contrast, the mostly unconditioned merger of the KIT and DRESS vowels, a feature limited in North America to Newfoundland, was not retreating at all. Similarly, Trudgill (1974) describes how the *maid/made* and *tow/toe* mergers were spreading from the London metropolitan area and were encroaching on the smaller urban center of Norwich. The first merger was nearly complete, while the second was advancing slowly. At the same time, the London influence was not preventing a local Norwich merger, that of the NEAR and SQUARE classes, from increasing. Pringle *et al.* (1981) discuss yet another case in which three mergers – those of *marry* and *merry* (i.e., TRAP and DRESS when followed by /r/ plus a vowel), of LOT and THOUGHT, and of NORTH and FORCE – were spreading from Ottawa, Canada, with its considerable nonlocal influence, to the surrounding Irish and Loyalist settlements.

Linguists since Otto Jespersen have assumed that mergers are irreversible. Labov (1994: 311) refers to this proposition as Garde's Principle, after the historical linguist Paul Garde, and states it as "Mergers are irreversible by linguistic means." A corollary, which he calls Herzog's Principle, states that "Mergers expand at the expense of distinctions" (Labov, 1994: 313). The cases noted above in which mergers spread into insular dialects illustrate Herzog's Principle. The notion that mergers are irreversible seems reasonable, since child language learners normally have no means of knowing which class words containing two merged vowels previously belonged to. Labov (1994) discusses several cases for which reversals of mergers were reported but for which there is good reason to think that the merger never actually happened. Perhaps the most noteworthy example is the reported merger of reflexes of Middle English /ɛ:/ and /a:/, as in *meat* and *mate*, respectively. Even though there is some evidence for such a merger in early Modern English, such as from rhymed poetry, it appears more likely that the two phones merely approached each other closely but never actually merged.

Nevertheless, mergers can occasionally be reversed through social developments. Such social pressures may arise from the influence of a standard dialect, making it prestigious for a speaker to exhibit two phones instead of one, or from heavy immigration that swamps the older inhabitants of an area. In the former case, lexical inconsistencies may be expected: that is, the merger is reversed for some words but not for others, and individual speakers may show idiosyncratic patterns. DeCamp (1958), for example, describes how Old English /æ/ and /æ:/ merged into /e/ and /e:/, respectively, in the Kentish and Mercian dialects, but then, when Wessex, where the mergers had never taken hold, became politically predominant, Mercian writers (and, presumably, speakers) unmerged the vowels in imitation of the West Saxon dialect. However, they showed lexical inconsistency and even hypercorrection, such as spelling *weg* 'way,' which had always had short /e/, as *wæg*. O'Cain (1977) reports an example of the latter case from Charleston, South Carolina, where the NEAR/SQUARE merger, formerly firmly established in the area, was being replaced by the distinction of those two classes because of extensive immigration from areas without the merger. Simultaneously, the migrants were giving the *pin/pen* merger, which did not previously occur in Charleston, a foothold there. Mergers that affect only a portion of a population are easier to reverse. In Texas, for example, some speakers born between the

World Wars – but, apparently, fewer than half of this birth cohort – merged the START and NORTH classes. This merger was reversed, however, and young Texans now show no sign of it. The reason was that there were competing systems, one of which drove out the START/NORTH merger. Some speakers merged NORTH with FORCE instead, while others kept all three classes distinct. The NORTH/FORCE merger, which has a much wider geographic distribution, ultimately prevailed (see Thomas, 2001, and other sources cited therein).

The perception of mergers has attracted occasional attention. One important study was Janson and Schulman (1983), who investigated the ability of speakers of two Swedish dialects to distinguish short /ɛ/ and short /e/ in Swedish. Speakers from Stockholm lacked the distinction, while speakers from Lycksele maintained it in their production. Janson and Schulman created synthetic stimuli that represented a phonetic continuum between short /i/ and short /a/ in a *sVt* frame and asked subjects to label each stimulus as *sit*, *set*, *sät*, or *sat*. *Sät* represented short /ɛ/ and *set* represented short /e/. The Stockholm natives showed little ability to distinguish the two, but, surprisingly, neither did the Lycksele natives. Janson and Schulman concluded that Lycksele natives could not access the short /ɛ/–short /e/ distinction in their perception. Labov *et al.* (1991) cast doubt on that conclusion on methodological grounds. Their basic contention was that labeling of stimuli is a conscious task and does not necessarily match perception in conversations. They devised their own experiment, which tested the ability of listeners to distinguish words such as *ferry* and *furry* as spoken by a Philadelphian. Such words are either merged or very similar in the white Philadelphia dialect. Instead of having listeners label the words, they created a story in which there was an ambiguity between *Merion* and *Murray in* and had listeners respond to the story. The results showed that, although non-Philadelphians were able to detect the distinction, Philadelphians were impaired in their ability to do so. Interest in how well individuals' production matches up with their perception of potentially merged vowels has continued, and that issue has been one of the major aims of Labov *et al.* (in press).

Another way in which the perception of mergers has been studied is through the use of commutation tests. A commutation test is a type of labeling task. However, listeners identify words uttered by a dialect speaker, usually of their own dialect. Commutation tests are useful not just for determining whether mergers have occurred, but also for investigating other vowel shifts. Examples are discussed in Labov *et al.* (1991) and Labov (1994). See Thomas (2002) for a more detailed review of the use of perception experiments in studying mergers.

Splits

Variationists have found phonemic splits difficult to study. The reason seems to be constraints imposed by more formalistic approaches to language. Splits ordinarily begin as phonetically predictable variants. Various factors, such as other sound changes and borrowing, may later create minimal pairs, at which time linguists acknowledge a phonemic split. However, it is quite possible that speakers could cease making a mental connection between allophones before minimal pairs exist, in which case the former allophones function psychologically as phonemes. This possibility, together with recent doubts about the psychological reality of phonemes, leads to uncertainty about when or if a split has actually occurred. As a result, experiments testing splits are rare.

When allophones in complementary distribution develop, what was formerly just a phonetic tendency becomes phonologized: that is, the phonetic targets come to differ depending on the phonological context. For example, speakers may differ in whether they have the process called Canadian raising phonologized. Some speakers merely show a statistical tendency to produce higher PRICE nuclei before voiceless consonants than elsewhere. On average, such speakers' nuclei show lower F_1 values in, e.g., *price*, *tight*, and *life* than in *prize*, *tide*, *five*, or *tie*, but the target values, which are usually apparent in realizations of the diphthong with long durations, are the same. Other speakers show different target values for the nucleus, e.g., *price* [pʰɹɜis] vs. *prize* [pʰɹaez], indicating phonologization of Canadian raising.

Allophonic splits have received more attention than phonemic splits. The fact that any conditioned sound change is an allophonic split makes them relatively easy to study. Some examples of allophonic splits have been especially well studied. One involves Canadian French vowels (Walker, 1984). In French, vowels may be short or long, depending on the prosodic and segmental context. In Canadian French, allophones with different qualities have developed depending on the length. High vowels are laxed in shortening contexts, e.g., *jupe* [ʒʏp] 'skirt,' while all vowels take on upglides in lengthening contexts, e.g., *pur* [pyɥʁ] 'pure.' In English, one of the most widespread allophonic splits is that of the GOOSE and GOAT vowels, mentioned above, into front allophones, which occur in most contexts, and back allophones, which occur mostly before /l/. A more localized split is that of TRAP/BATH in the New York City–Philadelphia–Baltimore area (see, e.g., Labov, 1994). In this area, a lax allophone, [æ], and a tense

allophone, [ɛə~ɛæ], have developed. The conditioning factors differ from city to city, though the lax allophone always occurs before voiceless stops, e.g. *pat* [pʰæʔt], and the tense allophone nearly always occurs before anterior voiceless fricatives (/f/, /θ/, and /s/), e.g., *pass* [pʰɛəs]. There has been some disagreement over whether this split is phonemicized.

Perceptual aspects of splits have received little attention. Guenter (2000) conducted an experiment in which he showed that Californians had difficulty or were totally unable to identify vowels before /r/, /l/, and /ŋ/ with vowels in other contexts. This finding suggested that there was no mental connection between, e.g., the vowel in *sing* and the vowels in either *sin* or *seen*, which would be tantamount to a phonemic split.

Methodological Issues

Data on ongoing vowel shifts and mergers have come from studies with a variety of designs. Some are classic sociolinguistic studies with a judgment sample or an ethnographic design, some follow dialectological methods, some are experimental, and some follow other designs. They also differ in the number of subjects, from case studies of a single person to surveys of a thousand or more respondents. Most focus on speech production, but a few examine perception.

Each of these types of design is suited for different research questions. Judgment samples work well for determining how vowel variation is related to demographic factors and what the trends seem to be across generations, while ethnographic surveys often provide a better picture of how speakers' identities are related to vocalic variation and change, and dialectological surveys are best suited for studying geographical variation. Panel studies, in which the same subjects are recorded periodically, are useful for determining whether individuals' vowels have changed, but are rarely conducted. For studying perception, experiments are nearly essential, and they can likewise be useful for examining some aspects of production, such as the effects of speech rate on vowel realization. Large-scale random samples, such as the one used by Bernstein (1993), are best for determining the overall makeup of a population. However, such surveys elicit mostly formal speech, a shortcoming that dialectological methods share to some extent, and thus the data they produce may be unrepresentative. Experiments may also elicit unrepresentative responses, depending on how they are designed.

For the most part, sociolinguistic studies exhibit an inverse relationship between the number of subjects in a study and the amount of information collected for each subject. Case studies normally produce large amounts of data for a few individuals and thus are well suited for investigating stylistic variation, the structure of speakers' vowel systems, and the effects of phonetic processes such as coarticulation and stress levels. However, they cannot address social or diachronic patterns within a community. At the other extreme, large random samples are generally unable to gather large amounts of data for individual respondents but can provide a reasonable picture of social, generational, and even geographical patterns.

The study of mergers presents some special methodological issues. One technique for determining whether a speaker shows a merger is simply to extract tokens of the potentially merged vowels from conversational speech. This method has the advantage of including more relaxed speech styles, which, according to a widespread assumption, represent a speaker's most natural speech. The two main disadvantages are that some vowels, especially where conditioned mergers are involved, may be too rare to occur reliably in an interview, and that the phonetic contexts of the words that happen to occur may differ, thus skewing the results. In some cases, accommodation to the interviewer's speech can also skew results. Another common technique, that of having subjects read minimal pairs such as *pool/pull* or *cot/caught*, solves the first two problems but introduces the possibility that speakers may self-monitor their utterances, showing mergers or distinctions that they do not produce in less monitored styles, especially if one of the affected vowels is subject to social prestige evaluation. Moreover, speakers tend to prolong vowels when reading lists of words, which will lead to less 'undershoot' of targets so that the tokens produced differ in formant structure from those encountered in conversational or other connected speech. A third approach, having subjects read specially constructed passages, mitigates the advantages and disadvantages of both conversation and minimal pairs. In addition to all those issues, there is also the question of whether a subject's production and perception of mergers coincide. This issue was discussed above in 'Mergers' with regard to Janson and Schulman (1983) and Labov *et al.* (1991).

In vowel analysis, another issue is whether the analysis is performed impressionistically or acoustically. Each method has its own pitfalls. Impressionistic phonetic transcription of vowel variation has a long history, beginning with dialect geography and continuing through many sociolinguistic studies, such as Labov (1963, 1966), Trudgill (1974), Horvath (1985), Eckert (1989), and Kerswill and Williams (2000). It is faster than acoustic analysis, meaning that more tokens can be sampled, and interspeaker normalization is not needed. However, it is subject to the vagaries of transcription norms by different

transcribers, to differing skill levels of transcribers, and to possible differences in the degree to which transcribers are affected by their own internal normalization mechanisms, which can result in undertranscription or overtranscription; see Thomas (2002) for a more detailed discussion. Acoustic measurements do not suffer from those problems and allow for much more precision, but they introduce other sources of error. Acoustic measurements of vowel formants, for example, are highly sensitive to the number of linear predictive coding (LPC) coefficients specified and to the quality of the original recording. The complexity of the acoustic correlates of speech sounds can mislead inexperienced researchers. Interspeaker normalization is essential for certain variables, particularly vowel quality, yet normalization has been a vexing problem for phoneticians and hence there is no such thing as a perfect normalization algorithm. Acoustic analysis equipment used to be expensive and cumbersome, but that problem has now vanished with the advent of free, downloadable software packages.

One final methodological issue for vowel analysis involves the attributes that are analyzed. Traditional impressionistic analysis of vowel variation focused on the quality of the nucleus, the direction of gliding (if any), and, to a lesser extent, the length. Acoustic analyses of vowel variation, following the lead of William Labov, have focused on analysis of the center frequencies of the first two formants, which are then plotted for comparison of different vowels. Furthermore, the quality of the nucleus has received the lion's share of attention. The quality of diphthong glides has attracted less interest. Other formant-related factors, such as bandwidth (indicative of, e.g., nasality and phonation) have been ignored. Formant trajectories have received sporadic attention, though problems in comparing different tokens have proved daunting. A closely related issue, the steady-state patterns of diphthong formants, has similarly not garnered much sustained interest. Measurement of vowel attributes besides formants remains incipient. Length, though easy to measure, has seldom been examined. Nor have breathiness and creakiness been analyzed often. Interactions between factors, such as between duration and/or amplitude and formant values or between fundamental frequency and formant values, offer possibilities for future work, too.

Prospects

Vowel shifting and merger can be expected to maintain their central position in studies of language variation. Several languages with rich traditions of dialectological and sociolinguistic investigation, including English, French, German, Dutch, and Scandinavian languages, also have complicated vowel inventories that engender shifting. The presence of research universities in countries where those languages are spoken, as well as the momentum that past work gives to ongoing efforts, ensures that vowel shifting in these languages will continue to be studied. Numerous details about the causes of vowel change remain to be worked out, but the ready availability of acoustic analysis programs and the continuing development of new methods for measuring such factors as breathiness and nasality will allow researchers to investigate these problems in new ways. More work should be conducted on vowel shifting in Third World languages, but perhaps the shortage of such studies can be remedied in the future as well.

Vurës

C Hyslop, La Trobe University, Bundoora, VIC, Australia

© 2006 Elsevier Ltd. All rights reserved.

Vurës, the name currently preferred by the speakers of the language, is referred to in Ethnologue as the Vetumboso or Vures dialect of Mosina. Mosina is a distinct language, now nearing extinction, with approximately eight speakers residing in the village of the same name, in the southeast of Vanua Lava Island, the Banks group of islands, northern Vanuatu. Vurës is now the dominant language spoken on the island, with upward of 1000 speakers. It is spoken predominantly in the villages of Vētuboso, Wasaga, and Kērēbētia and in smaller surrounding hamlets in the southwest of Vanua Lava. Like all languages of Vanuatu, Vurës is a member of the Oceanic subgroup of the Austronesian family. Within Vanuatu, it belongs to the Northeast Vanuatu-Banks Islands branch of the Northern Vanuatu linkage.

The languages of Northern Vanuatu tend to be fairly conservative Oceanic languages. Vurës has a number of features that are representative of the subgroup and others that are more distinctive. There are 15 consonants and nine vowels in the phonemic inventory, the number of vowels being quite high relative to other Oceanic languages. Notable features of the consonant inventory that are frequently observed in Oceanic languages are prenasalized voiced stops and a labialized labio-velar stop and nasal.

The language is nominative-accusative, with the grammatical relations subject and object being distinguished purely by AVO/SV word order. There is no marking of the subject and object within the verb phrase, which is unusual for an Oceanic language. Oblique arguments are mainly marked by prepositions and occur at the periphery of the clause. The language is both agglutinative and synthetic; however, compared to other Oceanic languages, there is not a great deal of morphology. There is very little inflectional morphology; aspect and negative polarity are marked by prefixes on the verb and by some particles. There are no tense distinctions. Derivational morphology is also limited, which is linked to the fact that many words are precategorial. This means that

It is spoken predominantly in the villages of Vētuboso, Wasaga, and Kērēbētia and in smaller surrounding hamlets in the southwest of Vanua Lava. Like all languages of Vanuatu, Vurës is a member of the Oceanic subgroup of the Austronesian family. Within Vanuatu, it belongs to the Northeast Vanuatu-Banks Islands branch of the Northern Vanuatu linkage.

The languages of Northern Vanuatu tend to be fairly conservative Oceanic languages. Vurës has a number of features that are representative of the subgroup and others that are more distinctive. There are 15 consonants and nine vowels in the phonemic inventory, the number of vowels being quite high relative to other Oceanic languages. Notable features of the consonant inventory that are frequently observed in Oceanic languages are prenasalized voiced stops and a labialized labio-velar stop and nasal.

The language is nominative-accusative, with the grammatical relations subject and object being distinguished purely by AVO/SV word order. There is no marking of the subject and object within the verb phrase, which is unusual for an Oceanic language. Oblique arguments are mainly marked by prepositions and occur at the periphery of the clause. The language is both agglutinative and synthetic; however, compared to other Oceanic languages, there is not a great deal of morphology. There is very little inflectional morphology; aspect and negative polarity are marked by prefixes on the verb and by some particles. There are no tense distinctions. Derivational morphology is also limited, which is linked to the fact that many words are precategorial. This means that

they can occur in their underived form as members of more than one word class; in particular, many roots occur as nouns and verbs. Further, many verbs are ambitransitive.

The marking of possession is a complex area of the grammar, a characteristic common to Oceanic languages. For nouns that are inalienably possessed, such as kinterms, body parts, and intimate possessions, the possessor is marked directly on the noun as a suffix. For other items, the possessor is marked on a relational classifier that indicates the function that the item has for the possessor. In Vurës there are six classifiers that mark the possessed item as food, drink, transport, domesticated plants and animals, clothing, or a general default category.

Complex predicates are commonly expressed in Vurës by verb serialization. A serial verb construction can combine verbs to express varied meanings and functions, such as causatives, abilitatives, directionals, and aspectual functions, and some less transparent functions. For example the verb *gial* 'to lie, pretend' can serialize with another verb to express the meaning of pretending to perform the action of the other verb.

Vygotskii, Lev Semenovich (1896–1934)

S A Romashko, Russian Academy of Sciences and Moscow State University, Moscow, Russia

© 2006 Elsevier Ltd. All rights reserved.

Born in Byelorussia, Lev Semenovich Vygotskiĭ studied at Moscow University from 1913 to 1917, gaining experience in a wide range of disciplines from medicine to law. His most vivid interest of this time concerned art and literature, and some of the elements of his early art criticism were later incorporated into his main psychological work. Returning to Byelorussia, Vygotskiĭ worked in Gomel as teacher and lecturer in different institutions, where he tried to reform the ways of teaching according to the new postrevolutionary situation. His interest in the process of knowledge transmission and assimilation led him more and more to the problems of psychology and symbolic interaction.

In 1924, Vygotskiĭ was invited to work at the Institute of Psychology in Moscow, where he started intensive research in different branches of psychology, psychophysiology, and related fields. His dissertation on psychology of art (1925, published only in 1965) recapitulated his early ideas of art (mainly literary) criticism, combined with new methodology of 'psychological reaction,' and tried to detect the objective principles of aesthetic function (as a specific 'aesthetic reaction') without reduction to other psychological mechanisms. After a short time, his life was overshadowed by two dangerous circumstances: mortal disease (he had tuberculosis) and growing political suppression of the Stalinist totalitarian regime transformed the last years of Vygotskiĭ's life into a race against time. He took every real opportunity to realize his ideas, working in different institutions in and outside Moscow. Vygotskiĭ prepared in 10 years almost 200 publications. On the other hand, this hectic situation of approaching different subjects in his passionate investigations caused serious hermeneutic problems for those who studied his theories later: it is clear that Vygotskiĭ's position was changing even during this short time, but there is no simple key to determine the development and general features of his varying positions.

Vygotskiĭ was one of the first people to detect the importance of aphasia for both psychology and linguistics, pointing to the connection between neurophysiology and early structuralism in linguistics (phonology as a pilot model for the study of speech disorders). These ideas were continued later by his disciple, A. R. Luria. Together with Luria and other adherents, Vygotskiĭ founded the so-called 'cultural–historical school' in psychology. The 'cultural–historical' approach tried to show the way out of a situation which Vygotskiĭ detected in the middle of the 1920s as a 'crisis in psychology.' The idea was to go beyond the physiology of I. S. Pavlov and create a more

Born in Byelorussia, Lev Semenovich Vygotskiĭ studied at Moscow University from 1913 to 1917, gaining experience in a wide range of disciplines from medicine to law. His most vivid interest of this time concerned art and literature, and some of the elements of his early art criticism were later incorporated into his main psychological work. Returning to Byelorussia, Vygotskiĭ worked in Gomel as teacher and lecturer in different institutions, where he tried to reform the ways of teaching according to the new postrevolutionary situation. His interest in the process of knowledge transmission and assimilation led him more and more to the problems of psychology and symbolic interaction.

In 1924, Vygotskiĭ was invited to work at the Institute of Psychology in Moscow, where he started intensive research in different branches of psychology, psychophysiology, and related fields. His dissertation on psychology of art (1925, published only in 1965) recapitulated his early ideas of art (mainly literary) criticism, combined with new methodology of 'psychological reaction,' and tried to detect the objective principles of aesthetic function (as a specific 'aesthetic reaction') without reduction to other psychological mechanisms. After a short time, his life was overshadowed by two dangerous circumstances: mortal disease (he had tuberculosis) and growing political suppression of the Stalinist totalitarian regime transformed the last years of Vygotskiĭ's life into a race against time. He took every real opportunity to realize his ideas, working in different institutions in and outside Moscow. Vygotskiĭ prepared in 10 years almost 200 publications. On the other hand, this hectic situation of approaching different subjects in his passionate investigations caused serious hermeneutic problems for those who studied his theories later: it is clear that Vygotskiĭ's position was changing even during this short time, but there is no simple key to determine the development and general features of his varying positions.

Vygotskiĭ was one of the first people to detect the importance of aphasia for both psychology and linguistics, pointing to the connection between neurophysiology and early structuralism in linguistics (phonology as a pilot model for the study of speech disorders). These ideas were continued later by his disciple, A. R. Luria. Together with Luria and other adherents, Vygotskiĭ founded the so-called 'cultural–historical school' in psychology. The 'cultural–historical' approach tried to show the way out of a situation which Vygotskiĭ detected in the middle of the 1920s as a 'crisis in psychology.' The idea was to go beyond the physiology of I. S. Pavlov and create a more

substantial and adequate base for an objective theory of the human mind, which should be a real Marxist psychology in Vygotskiĭ's opinion. The early stages of psychic development were always the main concern of Vygotskiĭ. Together with Luria, he wrote a book on the emerging mind, considering ape, 'primitive' man, and child as different aspects of early stages of psychic functions (Luria and Vygotskiĭ, 1930). Vygotskiĭ stressed the crucial role of language and other semiotic means as a specific universal instrument in human behavior, providing the basic condition for the development of the human mind and consciousness. Considering the early stages of language, Vygotskiĭ showed that these 'primitive' forms of linguistic activity are really very rich in possibilities, required by corresponding sociocultural situations.

Vygotskiĭ's main work, *Thought and language* (1934), was published shortly after his death. This book unified different aspects of Vygotskiĭ's work around the main point of his search: the dynamic functional interconnection of language and thought. Both are considered not as static entities, but as activities in a sociocultural context. Both are complex realities with an inner history: the language in its written form is another functional realization of linguistic activity, different from the oral speech and reflecting another stage of cultural (educational) development. The most original part of Vygotskiĭ's theory was the idea of inner speech as mediating dynamic mechanism between thought and language. Considering child development, Vygotskiĭ criticized J. Piaget, stressing that even the earliest stages of linguistic behavior are a part of social interaction: children are mastering language skills during their interaction with the social environment and as a part of practical mastering of reality. Children's way to thought and language is a way from external to inner behavioral activity.

Early death interrupted Vygotskiĭ's investigations, but saved him from very probable political repressions. A few years after his death, his ideas were totally banned from the official Soviet science. Only in the post-Stalinist period were Vygotskiĭ's ideas rediscovered in the Soviet Union, and they became more and more known in the West. The publication of *Psychology of art* (1965) attracted additional interest to Vygotskiĭ, showing a lesser-known part of his work. During the following decades, Vygotskiĭ's heritage produced wide discussions in psychology and linguistics (especially psycholinguistics). His work was considered from different positions: the psycholinguists and neurolinguists considered him as a founder of their disciplines; the structuralists and representatives of semiotics found in Vygotskiĭ their forerunner; and the cognitivists classified him as a 'precognitivist.' However, his systematic and functional approach to the old problem of thought and language, his ideas about linguistic behavior remain a productive avenue for linguistic analysis.

W

Wa

J Watkins, School of Oriental and African Studies, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The variety of Wa described here is known as Paraok/pərạ̈ɔk/ by the people who speak it, and is widely recognized as a standard form of the language. The scope of the name 'Wa' is complex, but it is the most inclusive and current among the many names used to refer to the speakers of Wa languages and also corresponds to the terms 佤 *Wǎ* in Chinese and in "ဝ" /wa̰/ in Burmese. Wa encompasses a cluster of some 40 dialects belonging to the Waic subgroup of the Palaungic branch of Northern Mon–Khmer languages and is spoken by up to about one million people living between the Salween and Mekhong rivers, an area straddling the border between northeastern Myanmar (Burma) and China's southwestern Yunnan province. About two-thirds of the Wa-speaking population live on the Burmese side of the border and one-third on the Chinese side; most Wa are bilingual in Burmese or Chinese, respectively.

The first Wa orthography intended for popular use was developed in the 1930s by the Baptist missionary Vincent M. Young, whose translation of the New Testament was published in the 1930s. Orthographies devised for Wa have used the Roman alphabet, sometimes with certain modifications. Young's orthography was ambiguous and inconsistent in a number of ways, for instance, by failing to represent the register contrast, final glottal consonants, and voiced/sonorants. It has been improved in recent years, however, by incorporating certain features of the phonologically faithful orthography developed by Chinese anthropologist-linguists in the 1950s, which is rather different in design. The most widely encountered orthographies may be compared in Table 1.

The syllable-initial consonants of Wa are set out in Table 2. Wa makes a 4-way voicing contrast in initial stops at 4 places of articulation, and has a range of breathy-aspirated sonorants. Complex initials are restricted to labial or velar stop + /l/ or /r/; final consonants are restricted to /p t c k/, nasals, /ʔ/, and /h/.

In Wa, as in other Mon–Khmer languages, the vowel inventory (Table 3) is effectively doubled because each vowel can occur in either of two registers, 'clear' and 'breathy,' analogous to the 'head' and 'chest' registers of Cambodian (Central Khmer). The register contrast in Wa, as in Mon–Khmer generally, has a complex of phonetic correlates, including

raɯʔ	>	^{ŋ}graɯʔ	deep	>	depth
pṳ	>	^{m}bṳ	thick	>	thickness
t̤iŋ	>	^{n}d̤iŋ	big	>	size
kiap	>	sə.^{ŋ}giap	pinch (v.)	>	clip (n.)
^{n}daiʔ	>	sə.^{n}daiʔ	eight	>	*no change in meaning*
^{ŋ}gaɯʔ	>	sə.^{ŋ}gaɯʔ	happy	>	*no change in meaning*

Table 7 Two Wa loanwords

pliʔ	mak.mṳŋ	ɲɛ̤ʔ	tɕau.sɯʔ
fruit	mango	house	classroom
Wa	Shan:ဓင်္ဂမုန်း; mak.muːŋ	Wa	Chinese: 教室 *jiàoshì*
= 'mango'		= 'classroom'	

fundamental frequency, vowel quality, phonation type, and vowel duration. The blend of these in any individual speaker's production of the register complex may vary. The register contrast cooccurs with final laryngeal consonants, as illustrated by the set of six words in Table 4.

The Wa system of personal pronouns (Table 5) retains dual number and contrasts inclusive and exclusive second-person pronouns.

In Wa, the Mon–Khmer morphological prefixation system has all but disappeared, leaving only a few nonproductive semisyllabic prefixes – of which by far the most common is /sə/ – and sound alternations that cover a broad, ill-defined range of functions, illustrated in Table 6.

Two characteristics of Wa syntax are that modifiers follow what they modify, as do relative clauses: thus 'the letter that I wrote,' from Table 1, is expressed as la̤i pɔ̤t ʔɤʔ '*letter [write I]*.' Secondly, VERB SUBJECT OBJECT word order is commonly observed: 'you read it' may be translated ^{ɲ}j^{ɦ}ak maiʔ nɔh '*read you it*,' though SUBJECT OBJECT VERB word order is also possible. Two sentences in Wa are shown in (1) and (2):

(1) hoc kɛʔ tin yṳh tiʔ
come 2PL here do what?
What did the two of them come here for?

(2) hoc tiʔ sɔ̤k pṳʔ ʔɤʔ
come SUBORD search younger. brother 1SG
They came to see my younger brother.

Wa is an isolating language, adept in the formation of periphrastic compounds. There has been extensive borrowing from Shan, and locally from Chinese and Burmese in areas where those languages are spoken. Loaned vocabulary is frequently supported by a generic Wa word, as in Table 7.

Functional literacy in Wa is very low. Wa speakers are much more likely to be literate in the national language of the country in which they live, although some villages may organize grassroots schooling, typically undertaken in a Christian context, and some schools in Wa-speaking China provide, in theory, five years of Wa-language education. Government schools in Burma must use only Burmese.

Wackernagel, Wilhelm (1806–1869)

K R Jankowsky, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Karl Heinrich Wilhelm Wackernagel was born in Berlin on April 23, 1806. He lost both parents in his early teens, exposing him to a life of severe hardship. Apart from the bleak economic outlook, matters turned extremely complicated by Wilhelm's involvement in the political upheaval following the defeat of Napoleon. In several letters to his older brother Philipp he elaborated on his ideas as to a more democratic government in Germany. The letters were intercepted, and the displeased authorities reacted harshly: Wilhelm, 15 years by then, was dismissed from his high school and eventually had to spend three days in Berlin's municipal prison. He was, however, given another chance and allowed to attend another high school. His infraction, though, was classified as *crimen laesae majestatis* (lese majesty), causing stigmatization as a 'demagogue,' which later on resulted in serious problems for his intended university career.

Wackernagel graduated from high school in fall 1824, having acquired superb knowledge in Latin, Greek, and French. His teachers characterized the level of his accomplishments in the older German literature as "bordering on literary learnedness." At Berlin University, where he concentrated on Old German and classical literature, his principal teacher was initially Friedrich Heinrich von der Hagen (1780–1856), soon to be replaced by Karl Lachmann (1793–1851), who influenced him greatly in numerous ways. Other teachers included August Boeckh (1785–1867) and Friedrich Hegel (1770–1831).

His economic situation grew from bad to worse, not, however, preventing him from maturing as a scholar. He started publishing during his student days. At the age of 22 he had established himself as a serious independent scholar in his field by editing *Das Wessobrunner Gebet* in 1827. The results of this research invalidated positions held by Jacob and Wilhelm Grimm and Wackernagel's teacher and friend Hans Ferdinand Massmann (1797–1874) in that he comprehensively identified form and meaning of one of the most important old German pieces of literature and proved its purely Christian origin.

At the end of his formal studies he was unable to pay the required fees for graduation. Since numerous job applications got nowhere, due to still being labeled "politically unreliable," he spend two years in Breslau at the invitation of his friend Hoffmann von Fallersleben (1798–1874). Upon his return to Berlin, things were not getting any better, in spite of the strongest endorsements by Lachmann, Jacob Grimm, and many others. Finally, a job offer arrived from Basel, Switzerland, and Jacob Grimm in his recommendation had stated that he did not know anyone better qualified for the position. Basel was willing to remedy Wackernagel's formal shortcoming, his lacking a D.Phil. degree, by offering him an honorary degree. But on his way to Switzerland in fall 1833

Wackernagel, Wilhelm (1806–1869)

K R Jankowsky, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Karl Heinrich Wilhelm Wackernagel was born in Berlin on April 23, 1806. He lost both parents in his early teens, exposing him to a life of severe hardship. Apart from the bleak economic outlook, matters turned extremely complicated by Wilhelm's involvement in the political upheaval following the defeat of Napoleon. In several letters to his older brother Philipp he elaborated on his ideas as to a more democratic government in Germany. The letters were intercepted, and the displeased authorities reacted harshly: Wilhelm, 15 years by then, was dismissed from his high school and eventually had to spend three days in Berlin's municipal prison. He was, however, given another chance and allowed to attend another high school. His infraction, though, was classified as *crimen laesae majestatis* (lese majesty), causing stigmatization as a 'demagogue,' which later on resulted in serious problems for his intended university career.

Wackernagel graduated from high school in fall 1824, having acquired superb knowledge in Latin, Greek, and French. His teachers characterized the level of his accomplishments in the older German literature as "bordering on literary learnedness." At Berlin University, where he concentrated on Old German and classical literature, his principal teacher was initially Friedrich Heinrich von der Hagen (1780–1856), soon to be replaced by Karl Lachmann (1793–1851), who influenced him greatly in numerous ways. Other teachers included August Boeckh (1785–1867) and Friedrich Hegel (1770–1831).

His economic situation grew from bad to worse, not, however, preventing him from maturing as a scholar. He started publishing during his student days. At the age of 22 he had established himself as a serious independent scholar in his field by editing *Das Wessobrunner Gebet* in 1827. The results of this research invalidated positions held by Jacob and Wilhelm Grimm and Wackernagel's teacher and friend Hans Ferdinand Massmann (1797–1874) in that he comprehensively identified form and meaning of one of the most important old German pieces of literature and proved its purely Christian origin.

At the end of his formal studies he was unable to pay the required fees for graduation. Since numerous job applications got nowhere, due to still being labeled "politically unreliable," he spend two years in Breslau at the invitation of his friend Hoffmann von Fallersleben (1798–1874). Upon his return to Berlin, things were not getting any better, in spite of the strongest endorsements by Lachmann, Jacob Grimm, and many others. Finally, a job offer arrived from Basel, Switzerland, and Jacob Grimm in his recommendation had stated that he did not know anyone better qualified for the position. Basel was willing to remedy Wackernagel's formal shortcoming, his lacking a D.Phil. degree, by offering him an honorary degree. But on his way to Switzerland in fall 1833

he passed through Göttingen and finally was awarded the degrees of Doctor of Philosophy and Magister of Liberal Arts. The Grimm brothers and three other friends had paid the fees. Two years after his arrival Wackernagel was appointed to a full professorship at Basel University.

Wilhelm Kosch (1958) called Wackernagel the most important Germanist of his time after the death of Jacob Grimm (1863). This evaluation is shared by many critics, and it ties in well with what Grimm himself thought of Wackernagel. In one respect, by being a poet of remarkable accomplishment, he even outdid Jacob Grimm. Those two activities cannot be separated, as Wackernagel's poetic oeuvre was largely based on his extraordinary knowledge of Old German literature. It did not take Wackernagel long to strike roots in his new country. In 1837 he was awarded honorary citizenship of Basel. He received numerous offers from German universities, but he showed no interest to return.

Wackernagel's publications centered around his work in class. His research was not primarily designed to identify significant problems waiting to be solved for the benefit of the general scientific community. He searched out, instead, what specific tools and instruments were needed for the benefit of his very specific clientele, his students. The three most important works of Wackernagel, the 3 volumes of *Deutsches Lesebuch,* the *Geschichte der deutschen Literatur bis zum dreissigjährigen Kriege,* and the *Poetik, Rhetorik und Stilistik: Academische Vorlesungen* are very convincing illustrations.

Apart from North Germanic languages he covered in his lectures and publications, he was expert in all areas of Germanic philology. Linguistic subjects stand beside literary and cultural subjects that ranged from early periods to the beginning of modern time. Both in lectures, and in his published research, he also dealt with comparative grammar involving German, Greek, and Latin. The quality of his research as well as its scope hold their own when compared with the publications of Grimm or scholars of equal reputation. Even today few of his writings are outdated and all of them make fascinating reading for those with the necessary background knowledge.

Wackernagel died in Basel on December 21, 1869.

Wagner, Heinrich (1923–1988)

G Mac Eoin, National University of Ireland, Galway, Ireland

© 2006 Elsevier Ltd. All rights reserved.

Born in Switzerland, Heinrich Wagner studied Indo-European philology in Zürich under Professors Manu Leuman and Julius Pokorny, Germanic philology under Rudolf Hotzenköcherle, and phonetics under Eugen Dieth. Under the influence of Pokorny he became interested in the Celtic languages and in 1945 came to Ireland to study Irish. Having spent some time in Dublin to improve his English, Wagner went to Dunquin, Co. Kerry, and soon acquired a knowledge of Irish. Thereafter he visited the other Irish-speaking districts and came to Telin in Donegal, and made the dialect of that area his own. There he became a close friend of Seán Ó hEochaidh, a collector of folklore for the Irish Folklore Commission. He was appointed Professor of Germanic Philology in Utrecht, The Netherlands, in 1951 and to a similar post in Basel, Switzerland, in 1953. He undertook in 1948 to compile a linguistic atlas of the Irish language and in the university vacations traveled the country by bicycle, interviewing speakers of Irish in remote districts and gathering the last remnants of the language in places where it had ceased to be the vernacular. He employed a questionnaire of 2000

he passed through Göttingen and finally was awarded the degrees of Doctor of Philosophy and Magister of Liberal Arts. The Grimm brothers and three other friends had paid the fees. Two years after his arrival Wackernagel was appointed to a full professorship at Basel University.

Born in Switzerland, Heinrich Wagner studied Indo-European philology in Zürich under Professors Manu Leuman and Julius Pokorny, Germanic philology under Rudolf Hotzenköcherle, and phonetics under Eugen Dieth. Under the influence of Pokorny he became interested in the Celtic languages and in 1945 came to Ireland to study Irish. Having spent some time in Dublin to improve his English, Wagner went to Dunquin, Co. Kerry, and soon acquired a knowledge of Irish. Thereafter he visited the other Irish-speaking districts and came to Telin in Donegal, and made the dialect of that area his own. There he became a close friend of Seán Ó hEochaidh, a collector of folklore for the Irish Folklore Commission. He was appointed Professor of Germanic Philology in Utrecht, The Netherlands, in 1951 and to a similar post in Basel, Switzerland, in 1953. He undertook in 1948 to compile a linguistic atlas of the Irish language and in the university vacations traveled the country by bicycle, interviewing speakers of Irish in remote districts and gathering the last remnants of the language in places where it had ceased to be the vernacular. He employed a questionnaire of 2000

items and visited 87 districts, including the Isle of Man. The maps provide a phonetic transcript of the informants' responses to the questionnaire. The first volume of the *Atlas* appeared in 1958, to be followed by three further volumes in 1964, 1966, and 1969. In 1958 he was appointed Professor of Celtic at the Queen's University, Belfast, a title that he later was permitted to change to Professor of Celtic and Comparative Linguistics. He remained in Belfast for over 10 years of the Troubles, but the repeated bombing of his department lessened his appetite for life there. In 1979 he accepted an appointment as Professor at the Dublin Institute for Advanced Studies. In the early 1980s he was diagnosed as suffering from a degenerative disease of the spine, and he died in Dublin in 1988.

Wagner's published work indicates his dual interests: linguistic typology and Celtic. His first publication was *Das Verbum in den Sprachen der Britischen Inseln*: *Ein Beitrag zur geographischen Typologie des Verbums* (1959a). This book consisted of two parts, the first being an examination of the verb in English, Irish, Scots Gaelic, and Welsh. This section is generally regarded as of high quality. The second part argued that a language of the Hamito-Semitic (Afro-Asiatic) type preceded the Celtic languages in Britain and Ireland. This part of his work has met with a mixed reception. The language that Wagner compared with the Celtic languages was Berber, which he had apparently learned from Ernst Lewy in Dublin. It is not clear that he had ever visited the Berber-speaking peoples of North Africa. His arguments are forceful but were written before the publication of Greenberg's *Language universals*. Today Wagner's work in this field is largely ignored, partly owing to the fact that it was not translated; this is not helped by the use by other writers of the word 'substratum' for the language that preceded Celtic in Britain and Ireland. Wagner (1959a, 242, n. 1) stipulated that the word could be used only of a known language that preceded another, as Irish is the 'substratum' of English in Ireland.

Wagner's greatest work was without doubt his *Linguistic atlas and survey of Irish dialects*. As a student of Hotzenköcherle, author of a Swiss linguistic atlas, he had become interested in linguistic geography, which is reflected in the title of another book of his: *Das Hethitische vom Standpunkt der typologischen Sprachgeographie* (1985). His *Atlas* was a huge task, accomplished within a few years and promptly published. In it he recounts the results of his journeys in Ireland, visiting places where Irish was spoken and choosing the best available speakers in each place as his informants. He presented his questionnaire to them and noted their answers in a phonetic script rather than recording them mechanically. The publication is in four volumes: Volume 1 has 300 maps showing words and phrases from the whole country; Volumes 2 through 4 have maps showing the answers to the questionnaire from Munster, Connacht, and Ulster/Isle of Man. The value of the *Atlas* is that it shows the state of the Irish language in the mid-20th century and rescues for future scholarship the last remains of the language in the western segment of the country. An index to the *Atlas* is currently being prepared at Queen's University, Belfast.

Another published work of his is *Gaeilge Theilinn: Foghraidheacht, Gramadach, Téacsanna* (1959b), a grammar of the dialect of Telin. It is much quoted but in fact is rather superficial, packing an account of the phonemics of the dialect, its morphology, syntax, and phraseology, with over 70 pages of texts and phonemic transcription, into 356 pages.

Wagner was essentially a typologist and linguistic geographer who strayed into dialectology and accomplished in a few years what Irish scholars had failed to do.

Wagner, Max Leopold (1880–1962)

G Price

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 9, pp. 4959–4960, © 1994, Elsevier Ltd.

Max Leopold Wagner was born on September 17, 1880 in Munich. He studied at the Universities of Munich, Würzburg, Paris, and Florence and then (1907–1910) taught modern languages at the German school in Constantinople, an experience that brought him into contact with such languages as Turkish, Arabic, and Judaeo–Spanish, all of which were to influence the course of his later researches. He also spent some time engaged on ethnological research in Mexico before taking up a teaching post at the University of Berlin (1915–1924). Apart from an appointment he held in the difficult period following World War II at the University of Coimbra (1947–1951, including a semester in 1948–1949 as visiting professor at Urbana, Illinois), he spent the rest of his career as an independent scholar, traveling extensively and acquiring an intimate knowledge of, in particular, the Mediterranean world and many of its languages and the associated cultures. He still holds an unchallenged position as an authority on the Sardinian language, on whose phonology, morphology, and lexicon he published a lengthy series of authoritative books (including an etymological dictionary), monographs, and articles. His other wide-ranging interests and publications cover, *inter alia*, the languages and literatures of Latin America, Judaeo–Spanish, African Latin (and its remnants in Berber), Greek and Arabic elements in the Romance languages, Gypsy languages, argot, and folklore. Malkiel (1963) draws attention, however, to his "strangely consistent reluctance to engage in French and Provençal studies or even to bring in Gallo–Romance collaterally." His work is characterized by a profound knowledge of the languages and cultures he is dealing with and his lexical work by a penetrating application of the 'word and thing' method. He spent the last years of his life, still engaged in research, in a house provided for him in Washington, DC, by a wealthy Italian–American businessman, and died on July 9, 1962.

Pilling (1894) attributed the term 'Wakashan' to Captain James Cook's observations in Nootka Sound in 1778 wherein he stated: "I would call them Wakashians, from the word *wakash*, which was very frequently in their mouths," (Cook, 1821: 308). Gallatin (in Pilling, 1894) first used the term to designate the Wakashan family and Boas (1890) solidified the boundaries of the family.

The Wakashan family is spread over Vancouver Island and the adjoining areas of the mainland, including northwestern Washington state and the central British Columbia coast.

Languages

The languages of the Wakashan family may be divided into two major subgroups, a northern and a southern group. The Northern group consists of four main languages: Haisla, Oowekyala and Heiltsuk (mutually intelligible), and Kwakwala (Kwakiutl), located on northeastern Vancouver Island and adjacent parts of the mainland north as far as Kitimat, British Columbia. Within the Northern branch, Kwakwala is the best documented, with an early grammar by Hall (1888) and another by Boas (1900). The most northerly language in the family is Haisla, with at least two dialects: Henaksiala and Haisla proper. Oowekyala is spoken by only a handful of people in the area of Rivers Inlet and is to a large extent mutually intelligible with Heiltsuk.

Wagner, Max Leopold (1880–1962)

This article is reproduced from the previous edition, volume 9, pp. 4959–4960, © 1994, Elsevier Ltd.

Max Leopold Wagner was born on September 17, 1880 in Munich. He studied at the Universities of Munich, Würzburg, Paris, and Florence and then (1907–1910) taught modern languages at the German school in Constantinople, an experience that brought him into contact with such languages as Turkish, Arabic, and Judaeo–Spanish, all of which were to influence the course of his later researches. He also spent some time engaged on ethnological research in Mexico before taking up a teaching post at the University of Berlin (1915–1924). Apart from an appointment he held in the difficult period following World War II at the University of Coimbra (1947–1951, including a semester in 1948–1949 as visiting professor at Urbana, Illinois), he spent the rest of his career as an independent scholar, traveling extensively and acquiring an intimate knowledge of, in particular, the Mediterranean world and many of its languages and the associated cultures. He still holds an unchallenged position as an authority on the Sardinian language, on whose phonology, morphology, and lexicon he published a lengthy series of authoritative books (including an etymological dictionary), monographs, and articles. His other wide-ranging interests and publications cover, *inter alia*, the languages and literatures of Latin America, Judaeo–Spanish, African Latin (and its remnants in Berber), Greek and Arabic elements in the Romance languages, Gypsy languages, argot, and folklore. Malkiel (1963) draws attention, however, to his "strangely consistent reluctance to engage in French and Provençal studies or even to bring in Gallo–Romance collaterally." His work is characterized by a profound knowledge of the languages and cultures he is dealing with and his lexical work by a penetrating application of the 'word and thing' method. He spent the last years of his life, still engaged in research, in a house provided for him in Washington, DC, by a wealthy Italian–American businessman, and died on July 9, 1962.

Wakashan

J Stonham, University of Newcastle, Newcastle upon Tyne, UK

© 2006 Elsevier Ltd. All rights reserved.

Pilling (1894) attributed the term 'Wakashan' to Captain James Cook's observations in Nootka Sound in 1778 wherein he stated: "I would call them Wakashians, from the word *wakash*, which was very frequently in their mouths," (Cook, 1821: 308). Gallatin (in Pilling, 1894) first used the term to designate the Wakashan family and Boas (1890) solidified the boundaries of the family.

The Wakashan family is spread over Vancouver Island and the adjoining areas of the mainland, including northwestern Washington state and the central British Columbia coast.

Languages

The languages of the Wakashan family may be divided into two major subgroups, a northern and a southern group. The Northern group consists of four main languages: Haisla, Oowekyala and Heiltsuk (mutually intelligible), and Kwakwala (Kwakiutl), located on northeastern Vancouver Island and adjacent parts of the mainland north as far as Kitimat, British Columbia. Within the Northern branch, Kwakwala is the best documented, with an early grammar by Hall (1888) and another by Boas (1900). The most northerly language in the family is Haisla, with at least two dialects: Henaksiala and Haisla proper. Oowekyala is spoken by only a handful of people in the area of Rivers Inlet and is to a large extent mutually intelligible with Heiltsuk.

Heiltsuk also has two dialects, spoken in Bella Bella and Klemtu, and there is some early work on it by Boas.

The Southern branch of Wakashan consists of three main languages: Nuuchahnulth (Nootka), Ditidaht (Nitinat), and Makah, located on the west coast of Vancouver Island and the tip of northwestern Washington state. Within each language there are various, mutually intelligible dialects. Nuuchahnulth is the most widely spoken of this group, constituting a chain of dialects ranging the length of the west coast of Vancouver Island from Brookes Peninsula to Barkley Sound. Ditidaht constitutes the southernmost Wakashan language on Vancouver Island. It has a close relationship with both the more northerly Nuuchahnulth and the more southerly Makah, which is the only Wakashan language spoken outside of Canada, in Washington state.

Recent estimates of the number of speakers of Wakashan languages vary from approximately 600 to 1200 speakers for all languages (Statistics Canada, 2003; Cook and Howe, 2004). (By comparison, there are estimated to be 1185 speakers of Gaelic languages in Canada.) Geographically, the Wakashan languages are adjacent to several other language families, including Athabaskan in the north, Chemakuan in the south, and Salish throughout the area.

Proto-Wakashan

Jacobsen (1979b) located the original home of the family on Vancouver Island or adjacent parts of the mainland, from which it has spread north and south. Swadesh (1953) proposed the Proto-Wakashan phoneme inventory shown in Table 1. Sapir (1921) suggested that Wakashan constituted one member, along with Salish and Chemakuan, of a Mosan subgroup, which, together with Kutenai and Algonquian-Ritwan, made up a larger superfamily. Swadesh (1962) noted similarities between Wakashan and Eskimo-Aleut, but little has been done to further any of this research recently (*see* **Areal Linguistics**). For a summary of work on the comparative-historical study of Wakashan, see Jacobsen (1979b).

Table 1 Proto-Wakashan phoneme inventory

p	t	ƛ[a]	c[b]		k		k^{ω}	q	q^{ω}	
b	d	λ	dz		g		g^{ω}	ɢ	$ɢ^{\omega}$	
ṗ	t’	ƛ’[a]	ċ[b]		k̓		$k̓^{\omega}$	q̓	$q̓^{\omega}$	ʔ
		ɬ	s		x		$x^{\omega d}$	x̣	$x̣^{\omega d}$	h
m	n	l	y[c]		γ		w			
ṁ	ṅ	l’	ẏ[c]		γ’		ẇ			
				i(:)		u(:)				
					a(:)					

[a]In IPA, /tɬ/ and /tɬ’/.
[b]In IPA, /ts/ and /ts’/.
[c]In IPA, /j/ and /j’/.
[d]In IPA, /χ/ and /$χ^{\omega}$/.

Phonology

The phonological inventory of all Wakashan languages consists of a large number of consonant phonemes and a relatively small number of vowel phonemes, usually with a vowel length distinction. In the Northern group there is a three-way distinction among obstruents, involving lax, glottalized, and voiced stops, whereas in the Southern branch there is only a lax versus glottalized distinction, with voiced stop reflexes of the original nasal phonemes appearing in Ditidaht and Makah.

Northern Wakashan has a long/short opposition in the vowel system, whereas the Southern group displays a three-way phonemic length distinction that is realized as a two-way contrast on the surface. The phonemic distinction is due to a third category of ‘variable-length’ vowels that are long in the first two syllables of the word but short elsewhere, as in *-naˇk* ‘have’ in ***łučnaak*** ‘have a wife’ versus *t’aṅanak* ‘have a child.’ Within Northern Wakashan, Oowekyala is purported to have glottalized vowels, which may appear only in the first syllable of a word. Howe (2000) provided minimal pairs such as *ma’łəla* ‘two people working together’ versus *małəla* ‘swimming’ and *ƛ̓a’s* ‘animal fat, oil, grease, blubber’ vs. *ƛ̓as* ‘far out at sea or seaward.’

In Northern Wakashan, the domain of primary stress assignment is the entire word, with stress assigned to the first heavy syllable or to the final vowel if no heavy syllable is encountered. In Southern Wakashan, the domain of primary stress is the first two syllables, with weight contributing to the placement. It should be noted that, although most Wakashan languages employ stress assignment, Kortland (1975) observed that Heiltsuk makes tonal distinctions instead.

Syllable structure is similar for all the languages, allowing complex codas but simple onsets. Boas (1947) stated for Kwakwala that “consonantic clusters do not occur in initial position. Monosyllabic stems are of the types CVC, CVCC, CVVC, CVVCC.” Southern Wakashan likewise involves an obligatorily filled onset (one and only one consonant) and potentially complex codas with up to three, or even four, consonants. Oowekyala appears to exhibit the most extreme cases of consonant clusters, according to Howe (2000).

The processes of glottalization (‘hardening’) and lenition (‘softening’) are quite unique in Wakashan and are invariably triggered by the attachment of a suffix to a base ending in a potential candidate for the

Table 2 Kwakwala lenition and glottalization[a]

Base		*Lenition*		*Glottalization*	
eep	'to pinch'	eeb.ayu	'dice'	eep̓.id	'begin to pinch'
wat	'to lead'	wad.əkʷ	'led'	wat'.eene̓ʔ	'act of leading
p̓əs	'to flatten'	p̓əy.aayu	'means of flattening'	p̓aap̓əc̓.a	'try to flatten'
məx	'to strike'	mən.ace̓	'drum'	maaməṅ.a	'ready to strike'
c̓uuł	'to be black'	c̓uul.atu	'black-eared'	c̓ul'.əmyu	'black-cheeked'

[a]/./ indicates morpheme boundary.
Source: Boas (1947).

change. In Southern Wakashan, glottalization affects both obstruents and sonorants, changing stops and affricates to their glottalized counterparts, fricatives to laryngealized glides, and sonorants to their laryngealized counterparts. Lenition, which affects only fricatives in Southern Wakashan, converts them to either /y/ or /w/, depending on whether they are labialized or not. These processes are more complex in Northern Wakashan. Boas (1947) provided the examples (somewhat modified for this presentation) from Kwakwala (Table 2).

One final phonological process worth noting is vowel epenthesis in Makah. In this language (and to some extent in the neighboring Ditidaht), there is a co-occurrence restriction against a voiced or glottalized consonant appearing in the onset of the second syllable when the coda of the first syllable is filled. The resulting cluster is broken up by inserting a lengthened copy of the vowel of the first syllable between the two consonants. Compare the Nuuchah-nulth forms, *c̓aqmis* 'tree bark' and *c̓usy̓ak* 'shovel' with the following Makah examples (from Davidson, 2002).

(1a) c̓aqaabis
c̓aq-bis
bark-collectivity.of
'tree bark'

(1b) c̓usuuyak
c̓us-yak
dig-thing.for
'shovel'

Other common phonological processes include labialization of back consonants, delabialization, and various forms of coalescence, syncope, and epenthesis.

Morphology

These languages are all highly polysynthetic, with complex morphophonemics, and rely heavily on suffixation. Reduplication is the only productive morphological operation that results in a preposed element. There are large numbers of both derivational and inflectional suffixes, but only one root may appear in each word, resulting in an absence of lexical compounding of the usual sort.

Table 3 Verbal suffixes in Kwakwala

Verb suffix	*Words*
-(g)ila	x̌eenagila
'to make'	'to make oil'
	x̌aawayuqʷila
	'to make a salmon weir'
-am̓ala	suupam̓ala
'to quarrel about'	'to quarrel over an axe'
	k̓əlkʷ am̓ala
	'to quarrel over a digging stick'
-(g)əλala[R]	haahaxagəλala
'to wear'	'to wear a shirt'

Source: Boas (1947). [R] indicates reduplication.

Lexical suffixes in Wakashan, unlike Salish, run the gamut of possibilities, including verbal, nominal, adjectival, locative, and adverbial functions. Perhaps the most interesting are the verbal morphemes, which interact with arguments within the sentence, resulting in their combination into a complex predicate, as illustrated in Table 3.

The last example in Table 3 illustrates another property of Wakashan suffixes: the ability of the suffix to trigger various effects on the stem to which they attach, including reduplication and vowel lengthening. The following examples from Makah illustrate these triggers (adapted from Davidson, 2002, where [L] indicates lengthening of the first vowel).

(2a) hihitaẋsʔiq
hita-ẋsa[R]-'iq
empty.root-in.bushes-DET
'in the bushes'

(2b) yuuxłapaal k̓ʷisii
yuxł-api[L]-' ax̌-'i k̓ʷisii
float-in air-TEMP=3.SING.IND snow
'snow is blowing in the air'

Reduplication is a highly productive process used to indicate a number of distinct grammatical categories. As shown in Table 4, it is employed in

derivation, aspect, and inflection as a marker of the distributive or plural, diminutive, and repetition or iteration and as a concomitant of certain derivational suffixes.

Wakashan also employs a set of classifiers that categorize nouns for the purpose of enumerating and qualifying, as well as in a pronominal function, as shown by the examples from Kwakwala in Table 5.

The various combinations of suffixes may result in rather long and complex words, as demonstrated by the examples from Nuuchahnulth in (3) (from Sapir and Swadesh, 1939. NOW 'contemporaneous,' SW 'switch reference,' CLS 'classifier').

(3a) ʔuuqχn̓uk̓ʷaχ'atquuč
ʔu -'aqχ -n̓ukʷ -'aχ -'at -quuč
REF -inside -inhand -NOW -SW -3S.CND
'if one is holding it' (Source: Sapir and Swadesh, 1939)

(3b) ʔaʔaʔaχqimɬḥtimyiɬm̓inḥʔaaqχeʔicuu
DUP- DUP- ʔaχ -qimɬ -ḥta -maɬ
REP- SUF two -CLS -onfoot[R] -move
-'iɬ -m̓inḥ -ʔaaqχ -(m)e-ʔicuu
-onfloor -PL -INTENT-2PL.IND
'You will carry two dollars on your feet' (Source: Sapir and Swadesh, 1955)

Syntax

Basic word order for Wakashan languages is, in general, head-initial, with VSO being the most common order. The degree to which individual languages allow the transposition of subjects and objects is one area of variation within the family. There is no case marking on nominals, but in some contexts complex prepositions may be used to indicate the grammatical role of arguments, as in the following example from Ditidaht (adapted from Klokeid, 1978).

(4) čuqʷšiχʔa ʔuxʷ John ʔuuyuqʷ Bill
hit NOM John ACC Bill
'John hit Bill'

Within the nominal phrase, quantifiers precede adjectives which, in turn, precede the head noun, as exemplified by the following examples from Nuuchahnulth (Rose, 1981). Relative clauses follow the head noun, as in (5b).

(5a) ʔiiḥ saya nism̓a
very distant land
'a really distant land'

(5b) ha xutaay [yaaqḥẇał naq Bill]
DET knife that.used Bill
'the knife that Bill used'

There are well-developed person-number inflectional paradigms that typically appear after the first position in the sentence in clitic-like fashion. Boas (1900: 715) remarked on "... the tendency of adverbs and auxiliary verbs to take the subjective ending of the verb, while the object remains connected with the verb itself. *k̓éeʔsən dúuquaq* not-I see-him, shows the characteristic arrangement of sentences of this kind."

Possession associated with the arguments of the clause is sometimes marked on the predicate, as shown in the examples in (6) from Kwakwala (Boas, 1900).

(6a) n̓eekən Gənəm
say.my wife
'my wife said'

(6b) n̓eekeexən Gənəm
say.he.my wife
'he said to my wife'

(6c) n̓eekeexees Gənəm
say.he.his wife
'he said to his (own) wife' (Boas, 1900)

Tense markers exhibit the special Wakashan characteristic of appearing on both nouns and verbs, leading to the common conclusion that there are no category distinctions in these languages (however, cf. Jacobsen, 1979a).

Table 4 Uses of reduplication in Kwakwala

Distributive/ plural	gʸuk 'house'	gʸigʸukʷ 'houses'
	n̓ala 'day'	n̓ən̓ala 'days'
Diminutive	t'eesəm 'stone'	t'at'edzəm 'small stone'
	bəgʷ 'man'	baabagəm 'boy'
Repetitive	meexa 'to sleep'	meemexa 'to sleep repeatedly'
	hanλa 'to shoot'	hanɬhanλa 'to shoot repeatedly'
With derivational suffix	-(g)əλala[R] 'to wear'	haahaxagəλala 'to wear a shirt'

Source: Boas (1947).

Table 5 Kwakwala classifiers

Number		*/-ukʷ/ 'person'*	*/-sgəm/ 'round object'*	*/-xλa/ 'dish, spoon'*
n̓əm	'one'	n̓əmukʷ	n̓əmsgəm	n̓əməxλa
m̓al	'two'	m̓al'ukʷ	m̓al'tsəm	m̓aləxλa
yud	'three'	yudukʷ	yuduxsəm	yudəxʷəxλa

Source: Boas (1947).

A form of syntactic compounding exists, at least in some members of the family, as illustrated by the following examples from Nuuchahnulth.

(7a) ʔiiḥʔii [yačmuut ǩaqmis]
the big bladder oil
'the large oil bladder' (Sapir and Swadesh, 1939)

(7b) [muunaa ńiiqńiiqaỷak]
machine sew -tool
'a sewing machine' (Sapir and Swadesh, 1955)

Wake Island: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

A North Pacific atoll of three coral islands built on top of an underwater volcano, Wake Island was annexed by the United States in 1899. In 1941 it was captured by the Japanese, it stayed in their hands for the duration of the war, and since 1974 it has been occupied by the U.S. military. In 1962, the President of the United States made the Secretary of the Interior responsible for the civil administration of the atoll. Military personnel have now left Wake Island, but a few contractor personnel remain. The official language is English.

Wales: Language Situation

H Bishop, Cardiff University, Cardiff, UK

© 2006 Elsevier Ltd. All rights reserved.

Wales (population 2 903 085) has two official languages, English and Welsh (*Cymraeg*). English is spoken by the vast majority of the population and became the dominant language around the turn of the 20th century, owing largely to rapid in-migration and internal migration from rural to urban areas brought about by industrialization. Welsh is spoken by approximately 20.5% of the population (2001 census), which represents an increase of approximately two percentage points on the 1991 census. Many see this increase as evidence of a halt in the decline in numbers of Welsh speakers that characterized the 20th century and as highlighting a general trend of revitalization.

Overall the status of Welsh is high, partly reflecting the language's increased instrumental value for employment – particularly in the media and the civil service, such as in the Welsh Assembly, which devolved from the United Kingdom government in London in 1999. The passing of a new Welsh Language Act in 1993 led to the establishment of the Welsh Language Board, which is charged with ensuring that the new Act is ever more strongly implemented. The Act provides a comprehensive statutory framework for the treatment of Welsh and English as co-equal in public life in Wales and as such all public-sector institutions are legally obliged to deal with the public bilingually. In recent years Welsh has achieved greater visibility within the linguistic landscape with many public notices, advertisements, signposts, and so on being bilingual.

The 1988 Education Reform Act ensures that Welsh is taught (up to the age of 16) in all but a few opt-out secondary schools in Wales as either a first or a second language. There is considerable and growing enthusiasm for Welsh-medium education at both primary and secondary level, with the majority of pupils now attending Welsh-medium schools coming from non-Welsh-speaking backgrounds.

The development of Welsh-language media has played a significant role in raising the profile of Welsh. The government-funded television channel S4C (Sianel Pedwar Cymru/Channel 4 Wales), established in 1982, broadcasts a mix of programming in Welsh for approximately six hours a day. The BBC also offers wide-ranging Welsh language broadcasting provision, both through radio and on the Internet, all of which are seen as key to the encouragement of the use of Welsh.

The demographic distribution of Welsh speakers around the county is uneven. While speakers in the predominantly rural north and west make up a higher proportion of the local population than in the more urban southern and eastern areas, in terms of absolute numbers, the largest population resides in the south and east. The continued attrition of Welsh in the 'heartland' areas of the north and west has led to at times acrimonious debate, centered largely on the threat of monoglot 'incomers' from England to these areas, with many (e.g., Cymuned [Community], a pressure group formed in 2001) calling for interventionist measures in the form of legislation, which would place limits on the sale of property in such areas to people outside Wales and restrict to local people the right to build new houses.

There is considerable and growing enthusiasm for Welsh-medium education at both primary and secondary level, with the majority of pupils now attending Welsh-medium schools coming from non-Welsh-speaking backgrounds.

The development of Welsh-language media has played a significant role in raising the profile of Welsh. The government-funded television channel S4C (Sianel Pedwar Cymru/Channel 4 Wales), established in 1982, broadcasts a mix of programming in Welsh for approximately six hours a day. The BBC also offers wide-ranging Welsh language broadcasting provision, both through radio and on the Internet, all of which are seen as key to the encouragement of the use of Welsh.

The demographic distribution of Welsh speakers around the county is uneven. While speakers in the predominantly rural north and west make up a higher proportion of the local population than in the more urban southern and eastern areas, in terms of absolute numbers, the largest population resides in the south and east. The continued attrition of Welsh in the 'heartland' areas of the north and west has led to at times acrimonious debate, centered largely on the threat of monoglot 'incomers' from England to these areas, with many (e.g., Cymuned [Community], a pressure group formed in 2001) calling for interventionist measures in the form of legislation, which would place limits on the sale of property in such areas to people outside Wales and restrict to local people the right to build new houses.

Walker, John (1732–1807)

L C Mugglestone, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

John Walker (1732–1807), actor, elocutionist, and lexicographer, was born in Colney Hatch in Middlesex, England. His early career was as an actor; beginning in the provinces, he later gained roles on the London stage in Drury Lane and at the celebrated Crow Street Theatre in Dublin. In his mid-30s, however, he determined on a change of career, becoming a schoolmaster at a school he established (with James Ussher) in Kensington in 1768. It was there that his interest in teaching the spoken language (and specifically elocution) developed, and from 1770 he began the first of his many public lectures on elocution. He toured Scotland and Ireland and gave lectures in many of the major cities of England. In 1774 he published *A general idea of a pronouncing dictionary of the English language on a plan entirely new,* which aimed to add the marking of pronunciation to dictionary entries by using a system of respelling and numerical diacritics. His wider ambition, however, was the standardization of pronunciation, and he regarded what he termed 'the vices of custom' with distaste. His later *Critical pronouncing dictionary and expositor of the English language*, first published in 1791, was the fulfillment of his aims; in it he stressed the virtues of analogy, regularity, and consistency in speech. As he proclaimed (1791: vi), "If the analogies of the language were better understood, it is scarcely conceivable that so many words in polite usage would have a diversity of pronunciation, which is at once so ridiculous and embarrassing." Later regarded as the 'statute book of English orthoepy,' the *Critical pronouncing dictionary* went into three further editions during Walker's own lifetime and was reprinted numerous times over the course of the 19th century. In it Walker provided specific advice for the inhabitants of Scotland, with a similar section for those of Ireland and the Cockney inhabitants of London. He also provided a detailed phonetic investigation of the sounds of speech in the late 18th and early 19th centuries; although often prescriptive in intent, this work contains a mass of information on the speech patterns of the time, as well as on the contemporary interest in the establishment of a non-localized accent. Regarded with some skepticism by writers later in the century ("how does Mr. John Walker, of Colney Hatch, determine the usages of . . . the three classes he has named?", as the phonetician Alexander Ellis contended), he was nevertheless acknowledged to be a widely influential figure. His other publications include *A dictionary of the English language, answering at once the purposes of rhyming, spelling and pronouncing* (1775), which, aside from its poetic utility, also aimed to establish an invariant pronunciation for each word; his *Elements of elocution* (1781) was widely regarded as the first practical treatise on the art of speaking. Known as 'Elocution Walker' during his lifetime, his principles were often implemented in the teaching of the spoken language in 19th-century educational work.

Wallis and Futuna: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

With the Fijis to the west and Samoa to the east, the South Pacific territory of Wallis and Futuna comprises two archipelagos with three main islands: Wallis (Uvea in Polynesian), Futuna, and Alofi, where, however, the scarcity of water renders permanent settlements impossible. During the 15th century, Wallis was settled by Polynesians from Tonga, while those that settled on Futuna came from Samoa. The two islands were visited by European navigators in the 17th century, but European presence of any note did not start until the 19th century. The three kingdoms of Uvea, Alo, and Sigave – the last two on Futuna – signed a treaty with France and became a French protectorate in 1887. Wallis and Futuna were used as a military base for U.S. forces during World War II. In 1959, the inhabitants of the islands chose by referendum to become a French overseas territory. French is the official language of Wallis and Futuna and it is used in most political, administrative, and legal situations, but the majority of people are bilingual and on Wallis nearly all islanders speak Wallisian as their first language; the same is true for Futuna, where almost all the inhabitants have East Futuna as their mother tongue. Both languages belong to the Eastern Malayo-Polynesian group, but the differences between Wallisian and East Futuna are significant enough to make intercommunication virtually impossible. Furthermore, both languages present local varieties, which differ phonologically and lexically, but are still mutually intelligible. Wallisian, and to a lesser extent East Futuna, show a higher register used for communication with kings, ministers, and the Christian God (missionaries were sent to the islands during the 19th century to convert the populace). It must be noted that there are more Wallisians and Futunans on New Caledonia nowadays than on Wallis and Futuna, as there has been steady migration toward this other French overseas territory: 17 563 on New Caledonia versus 14 166 on Wallis and Futuna (2004). Despite a new (December 2000) French law that has been designed to aid the promotion of local languages in overseas possessions, education on Wallis and Futuna is still mainly conducted in French using material compiled in France, a fact that leads to low levels of literacy, as the majority of children are schooled in a language that is foreign to them. As for the media, French still dominates, but there are efforts to broaden the horizon to the other languages, Wallisian and East Futuna. For example, in 1995 a trilingual weekly paper was launched. Also, the local radio station broadcasts daily in the three languages and on television there are news summaries in the local languages. As a last note: France has just signed the European Charter of Regional or Minority Languages; this will per force entail fundamental changes in France's language policies in its overseas territories.

Wallis, John (1616–1703)

W Viereck, Universität Bamberg, Bamberg, Germany

© 2006 Elsevier Ltd. All rights reserved.

John Wallis was a remarkable scholar. He was born in Ashford, Kent, in 1616. In 1630 he was sent to Felsted School in Essex, where he learned Latin, Greek, and some Hebrew and where he made his first acquaintance with mathematics. In 1632 he went to Emmanuel College, Cambridge, where he received his B.A. in 1637 and his M.A. in 1640. In the same year he was ordained in the Church of England. In 1642 Wallis began assisting the Parlamentarians in deciphering captured Royalist documents, and in 1643 he was rewarded by being made rector of a church in London. Wallis joined the moderate Presbyterians in signing the remonstrance against the execution of Charles I, for which he incurred the lasting hostility of the Independents. In spite of their opposition he was appointed in 1649 to the Savilian chair of geometry at Oxford University, which he held until his death in 1703. In 1654 Wallis received a D.D. degree. When Charles II was restored to the throne in 1660, Wallis was made one of the royal chaplains. He was one of the Divines appointed in 1661 to revise the Book of Common Prayer, was a founder–member of the Royal Society, whose first Charter was given by the King in mid-1662, and published many articles in its *Philosophical Transactions*. In 1689, when William III acceded to the throne, Wallis took an oath of allegiance and was appointed royal decipherer. In 1692 he was consulted about the Gregorian calendar and advised against it, so that it was not adopted.

Apart from works on logic, theology, and cryptography, Wallis contributed immensely to mathematics. *Arithmetica infinitorum* (1655), *Mathesis universalis* (1657), and *De algebra tractatus* (1685) are his most important works in this field. Wallis extended the application of Johannes Kepler's law of continuity, anticipated differential and integral calculus, and introduced the symbol for infinity.

Outside mathematics, Wallis's most influential work is a book on the grammar of English, *Grammatica linguae Anglicanae* (1653). Here Wallis adopted a modern approach. He was the first to disclose the structure of English by detaching himself from the system of Latin. There is hardly anything in Wallis's grammar that resembles the Latin-based paradigms of declensions and conjugations. Wallis's book is also very important in the teaching of pronunciation. Unlike most of his predecessors, he did not intend to improve orthography. Rather, he wanted to teach pronunciation, first by comparing English sounds with those of other languages, not just French or German, but also Arabic, Hebrew, and Greek, and second by incorporating the individual sounds into a system. Wallis founded scientific phonetics. He also applied his phonetic insights to the teaching of deaf-mutes; in fact, he was the first to devise such a system.

In his treatise *De loquela; sive de sonorum omnium loquelarium formatione: tractatus grammatico-physicus,* prefixed to the grammar, Wallis established for the first time a system of sounds according to their articulation. The *vocales* are arranged according to (1) their degree of aperture into wide, medium, and narrow and (2) their place of articulation in *gutturales, palatinae,* and *labiales*. The *consonae* are differentiated according to (1) their manner of articulation in *mutae, semimutae,* and *semivocales* and (2) their place of articulation as the vowels. The following is Wallis's description of the difference between [n] and [ŋ]:

> The pronunciation of *n* always involves the tip of the tongue striking the front of the palate, near the roots of the upper teeth; whereas in the latter the tip of the tongue is normally moved down to the roots of the lower teeth, and the back of the tongue is raised up to the back of the palate, blocking the sound at this point. That is to say, it has the same articulation in the mouth as *g*, but the direction of the breath is the same as for *n* (tr. by Kemp in Wallis, 1972: 161).

As to his grammatical insights, the following points deserve to be mentioned. As regards number, Wallis makes mention of *clōth–clōthes* and *path–pathes*, but he is the first to mention the alternation s/z in *house* [haus]–*houses* [hauziz]. He recognizes only two tenses for English, present and past, on formal grounds; moods disappear altogether. *Shall* and *will* indicate the future. Before Wallis, no grammarian assigned different functions to these two forms. He said,

> It is difficult for foreigners to know when to use the first form and when the second . . ., and no other description that I have seen has given any rules for guidance, so I thought I ought to give some. . . . In the first person *shall* simply indicates a prediction, whereas *will* is used for promising or threatening. In the second and third persons *shall* is used for promising or threatening, and *will* of a straightforward prediction (tr. by Kemp in Wallis, 1972: 339).

By 1699 Wallis's grammar had appeared in five editions; even after his death it was reprinted four times until 1756. Then, however, during the period of comparative historical linguistics his synchronic approach became outmoded. That his grammar is a true classic of linguistics is also documented by the fact that three centuries after its first publication the Latin original appeared again in facsimile together

with an English translation and an extensive commentary by J. A. Kemp (Wallis, 1972).

Wambaya

R Nordlinger, University of Melbourne, Melbourne, Australia

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Wambaya is a non-Pama–Nyungan language of northern Australia (of the Mirndi group), originally spoken in the Barkly Tablelands region of the Northern Territory. The Wambaya people suffered greatly from the invasion of their land, their subsequent removal from their traditional country, and the dispersal of their community. As a result of these and other factors, the Wambaya language has now almost disappeared. There are only a handful of (semi-)speakers remaining, most of whom live in the towns of Tennant Creek, Elliott, and Borroloola. Wambaya is closely related to two further dialects – Gudanji and Binbinka. Gudanji is in much the same state as Wambaya with only a handful of (semifluent) speakers left; and there are no longer any remaining speakers of Binbinka.

Like all Australian languages, Wambaya was not traditionally written, and so the earliest records we have of the language are those collected by white researchers since the early 20th century. Some lexical items were recorded by Mathews (1900, 1908) and by Spencer and Gillen (1904), largely concerning the kinship system. The first detailed grammatical information for Wambaya is found in the field notes recorded by Ken Hale in 1959 (Hale, 1959, 1960) and is continued in Neil Chadwick's work on the whole Barkly language group (including also Jingulu [Djingili] and Ngarnka [Ngarndji]) dating from the 1970s (Chadwick, 1978, 1979, 1984, 1997). My own fieldwork on the language began in 1991 and has so far resulted in the publication of a grammar of Wambaya (Nordlinger, 1998a), the development of a dictionary and learner's guide (Nordlinger, 1998b, 1998c), and a number of articles (Nordlinger, 1995, 2001; Nordlinger and Bresnan, 1996; Green and Nordlinger, 2004). The grammatical features discussed in this brief article are all discussed and exemplified in greater detail in Nordlinger (1998a).

Phonology

Phonologically, Wambaya is a typical Australian language, with five places of articulation for stops, including two apical series (apico-alveolar and retroflex) and one laminal series. There is no voicing contrast. There is a nasal corresponding to each stop articulation, and three laterals (in the nonperipheral places of articulation). There are three vowel phonemes, and no productive length distinction. The phoneme inventory and the orthographic symbols corresponding to each phoneme are provided in **Table 1**.

All Wambaya words are minimally disyllabic and virtually always vowel-final. (The one exception is the auxiliary, see below, which can end in a consonant if it contains one of three nasal-final affixes: *-any* 'direction away, past tense,' *-amany* 'direction towards, past tense,' or *-n* 'progessive aspect'.) Primary stress is generally on the first syllable of the word. Words can begin with a vowel (as in *alaji* 'boy'), or a consonant (*daguma* 'hit,' *juwa* 'man,' *ngajbi* 'see'). There are no words beginning with the consonants *r* [ɹ], *rr* [ɾ/r], *ly* [ʎ] and further, as is common among Australian languages, the distinction between the two apical series is neutralized in initial position. Initial apicals are all represented orthographically as apico-alveolars (*d, n, l*). Biconsonantal clusters are common, but only word-medially. Such clusters usually contain an apical or laminal consonant followed by a labial or dorsal consonant (e.g., ***anm**urru* 'cuddle,' ***bardg**u* 'fall,' ***marrg**ulu* 'egg,' ***ngajb**i* 'see,'

with an English translation and an extensive commentary by J. A. Kemp (Wallis, 1972).

Some lexical items were recorded by Mathews (1900, 1908) and by Spencer and Gillen (1904), largely concerning the kinship system. The first detailed grammatical information for Wambaya is found in the field notes recorded by Ken Hale in 1959 (Hale, 1959, 1960) and is continued in Neil Chadwick's work on the whole Barkly language group (including also Jingulu [Djingili] and Ngarnka [Ngarndji]) dating from the 1970s (Chadwick, 1978, 1979, 1984, 1997). My own fieldwork on the language began in 1991 and has so far resulted in the publication of a grammar of Wambaya (Nordlinger, 1998a), the development of a dictionary and learner's guide (Nordlinger, 1998b, 1998c), and a number of articles (Nordlinger, 1995, 2001; Nordlinger and Bresnan, 1996; Green and Nordlinger, 2004). The grammatical features discussed in this brief article are all discussed and exemplified in greater detail in Nordlinger (1998a).

Phonology

Phonologically, Wambaya is a typical Australian language, with five places of articulation for stops, including two apical series (apico-alveolar and retroflex) and one laminal series. There is no voicing contrast. There is a nasal corresponding to each stop articulation, and three laterals (in the nonperipheral places of articulation). There are three vowel phonemes, and no productive length distinction. The phoneme inventory and the orthographic symbols corresponding to each phoneme are provided in Table 1.

All Wambaya words are minimally disyllabic and virtually always vowel-final. (The one exception is the auxiliary, see below, which can end in a consonant if it contains one of three nasal-final affixes: *-any* 'direction away, past tense,' *-amany* 'direction towards, past tense,' or *-n* 'progessive aspect'.) Primary stress is generally on the first syllable of the word. Words can begin with a vowel (as in *alaji* 'boy'), or a consonant (*daguma* 'hit,' *juwa* 'man,' *ngajbi* 'see'). There are no words beginning with the consonants *r* [ɹ], *rr* [ɾ/r], *ly* [ʎ] and further, as is common among Australian languages, the distinction between the two apical series is neutralized in initial position. Initial apicals are all represented orthographically as apico-alveolars (*d, n, l*). Biconsonantal clusters are common, but only word-medially. Such clusters usually contain an apical or laminal consonant followed by a labial or dorsal consonant (e.g., ***anm**urru* 'cuddle,' *bar**dg**u* 'fall,' *mar**rg**ulu* 'egg,' *ngaj**b**i* 'see,'

Table 1 Wambaya phonemes

Consonants	*Bilab.*	*Apico-alv.*	*Apico-postalv. (retroflex)*	*Lamino-palatal*	*Velar*
Stop	b (b)	d (d)	ɖ (rd)	ɟ (j)	g (g)
Nasal	m (m)	n (n)	ɳ (rn)	ɲ (ny)	ŋ (ng)
Lateral		l (l)	ɭ (rl)	ʎ (ly)	
Tap/Trill		ɾ/r (rr)			
Semivowel	w (w)		ɹ (r)	j (y)	
Vowels	i (i) (i: (ii))		u (u)		
		a (a) (a: (aa))			

mangan**ym**a 'tucker, nonmeat food'), but other combinations are possible also (*bu**ngm**aji* 'old man,' *wu**gb**ardi* 'cook'). There is one triconsonantal cluster *rrgb* (*lu**rrgb**anyi* 'grab,' *gu**rrgb**arra* 'stare').

A brief discourse in the language written in the conventional orthography is provided in (1). This example illustrates many of the grammatical properties to be discussed below.

(1) Yarru ngurr-any gurdi-nmanji ngaj-barda.
go.NF *1*PL.INC-PST.AWAY *bush*.IV.OBL-ALL *see*-INF
Gannga ngurr-amany bangarnigadi.
return.NF *1*PL.INC-PST.TWDS *this way*
Gurijba gi-n mirra
good.IV.NOM *3*SG.S.PRES-PROG *sit*.NF
ngarrga maga.
my.IV.NOM *house*.IV.NOM
'We went to the bush to have a look (at my house). Then we came back this way. My house is fine.'

Morphology

Wambaya, being one of the southernmost non-Pama–Nyungan languages, is typologically atypical in having lost virtually all prefixing morphology (see Nordlinger, 1998a; Green and Nordlinger, 2004; Harvey *et al*., to appear for discussion). All productive morphology is suffixing. Like many other Australian languages, Wambaya has extensive case and agreement morphology – all elements of an NP must show concord in gender, number, and case – and 'free' (i.e., pragmatically determined) word order.

The two open word classes are verbs and nominals. Concepts translated into European languages as adjectives are split across these two classes. For example, *bulyingi* 'small,' *bugayi* 'big,' *gurijbi* 'good,' and *bagijbi* 'bad' are nominals, while *baliji* 'be hungry,' *gurda* 'be sick,' and *laji* 'be quiet' are intransitive verbs. Verbs are characterized by the fact that they must always cooccur with the auxiliary (see below), which carries subject/object agreement information and tense/aspect/mood for the clause. Verbs have only a small amount of inflectional morphology, contrasting future/imperative, and nonfuture (unmarked) forms. This lack of morphology appears to result from the fact that these are historically derived from uninflected coverbs, with the synchronic auxiliary being the original inflected main verb (see Green and Nordlinger, 2004 and below for discussion). There are two inflectional classes for verbs, membership of which is phonologically conditioned. Vowel-final verb stems belong to the J-class of verbs, consonant-final verb stems belong to the Ø-class of verbs (and there are, of course, a dozen or so irregular verbs that don't follow the pattern of either class). These classes are distinguished by the fact that in the J-class, there is a thematic *-j-* added before any verbal affixes, while there is no thematic consonant in the Ø-class. The two classes also have different nonfuture tense inflections. Examples of the two paradigms are:

(2) *daguma-* 'hit' (J-class): *daguma* (nonfuture), *daguma-j-ba* (future/imperative), *daguma-j-barda* (infinitive)

(3) *gulug-* 'sleep' (Ø-class): *gulug-bi* (nonfuture), *gulug-ba* (future/imperative), *gulug-barda* (infinitive)

In contrast to verbs, nominals have a large amount of morphology. As is relatively common among northern Australian languages, there are four genders – masculine (class I), feminine (class II), vegetable (class III) (including nonmeat food and some body parts), and neuter (class IV) (residue). These genders are marked on nominals and their modifiers by suffixes, and are marked on demonstratives by cognate prefixes (vestiges of the earlier prefixing system, see Green and Nordlinger, 2004 and Harvey *et al*., to appear for discussion). Example (1) above shows concord with adjectives (*gurijba* 'good.IV') and possessive pronouns (*ngarrga* 'my.IV'). That these forms are truly agreeing with the head nominal *barrawu* 'house' can be shown by contrast with the following example in which they are agreeing instead with a class I nominal *janji* 'dog.'

(4) yini ngarri janji gurijbi
this.I *my*.I *dog*.I *good*.I
'this is my good dog'

Nominals are also inflected for number – dual and plural – although since the unmarked nominal can have singular, dual, or plural interpretations, this inflection is optional. Pronouns (a subclass of nominals) distinguish singular, dual, and plural numbers and make an inclusive/exclusive distinction in the 1st person nonsingular.

Nominals are obligatorily inflected for case. Wambaya is what has been called a 'split-ergative' language. Nominals inflect according to an ergative/absolutive distinction, while pronouns inflect largely on a nominative/accusative pattern. We can, therefore, distinguish three distinct case contrasts, as in Table 2, where A stands for 'transitive subject,' S for 'intransitive subject,' and O for 'transitive object.' In the following table, the shading indicates homophony between forms; thus, nominals have homophonous nominative and accusative forms, while pronouns have homophonous ergative and nominative forms.

As well as the three core cases shown in Table 2, there are nine further cases in Wambaya, including: dative, ablative, allative, comitative, genitive, proprietive, privative, perlative, causal, and originative. The ergative case additionally covers locative and instrumental functions. Gender markers also distinguish case, having one form before cases with zero realizations (i.e., the nominative and the accusative), and another form (called the 'oblique' form) before all other cases. For example, *jan-ji* 'dog-I.NOM' vs. *ja-nyi-ni* 'dog-I.OBL-ERG'; *guji-nya* 'mother-II.NOM' vs. *guji-ga-nka* 'mother-II.OBL-DAT'; *mangany-ma* 'food-III.NOM' vs. *mangany-mi-nka* 'food-III.OBL-DAT.'

All verb-headed clauses in Wambaya must contain a grammatical auxiliary containing subject and object cross-referencing bound pronouns and clausal tense/aspect/mood information. While word order is grammatically free in Wambaya for the most part, the auxiliary is unusual in having a fixed position: it must always occur in second position in the clause (after the first constituent, which may be a single word or a complex NP). The auxiliary appears to have derived from a fully inflecting verb with pronominal agreement prefixes and tense/aspect/mood suffixes. An original main verb–coverb structure (as is common in other northern Australian languages, see McGregor, 2002), has become an auxiliary-verb structure in Wambaya, with the auxiliary retaining only the grammatical information of the original main verb, and the original coverb now contributing all lexical meaning. Remnants of an original main verb are found in the directional/tense portmanteaux in the synchronic auxiliary, as in the contrast between *ngurr-any* '1PL.INC-PST.AWAY' and *ngurr-amany* '1PL.INC-PST.TWDS' in (1). Examples of auxiliaries in transitive and reflexive/reciprocal clauses include the following:

Table 2 Wambaya core case system

	A	*S*	*O*
Nominals	Ergative	Nominative	Accusative
Pronouns	Ergative	Nominative	Accusative

(5) Garndani-j-ba nyi-ngg-a! Daguma
shield-TH-FUT *2*.SG-RR-NF *hit*.NF
gunu-ny-u ninki!
3.SG.M.A-*2*O-FUT *this*.I.SG.ERG
Shield yourself! He's going to hit you!

As shown by the second clause in (5), the interaction between the tense marking on the auxiliary and the verb is complex, and under certain conditions the two may encode different tense values, together defining the tense/mood value for the clause as a whole. See Nordlinger and Bresnan (1996) and Nordlinger (1998a) for detailed discussion.

Syntax

Wambaya exhibits the three classic properties of 'nonconfigurationality' (Hale, 1983): 'free' word order, null anaphora, and discontinuous constituents. Core NPs are generally optional – the reference of the subject and object being retrievable from the bound pronouns in the auxiliary – and thus Wambaya sentences commonly consist of simply a verb followed by the auxiliary as in (6). Nominal modifiers can appear separately to the heads they modify, their coreference indicated by gender, number, and case agreement (7).

(6) Ngaj-bi irri-ng-a.
see-NF *3*PL-*1*O-NF
'They're looking at me.'

(7) **Nganki** ngiy-a lurrgbanyi
this.SG.II.ERG *3*.SG.F.A-PST *grab*.NF
wardangarri-nga-ni.
moon-II.OBL-ERG
'This moon grabbed (her).'

Case marking occurs on nonfinite verbs in subordinate clauses to encode relative tense and, in some cases, switch reference. In (8), the use of the ergative/locative case in the subordinate clause (here in initial position) signals that the two events are cotemporaneous (relative present tense) and that the subject of the subordinate clause is coreferential with the subject of the main clause. In (9), the infinitive marker is used in a cotemporaneous subordinate clause to signal that the subordinate subject is coreferential with the main clause *object*.

(8) Ngarli-ni irri-ng-a ngurra abajabajami.
talk-LOC *3*.PL-*1*O-NF *1*.PL.INC.ACC *make.crazy*.NF
'They make us confused (when they're) talking.'

(9) Ngaj-bi ng-a gaj-barda.
see-NF *1*.SG-PST *eat*-INF
'I saw him eating.'

Switch reference is not encoded in purposive clauses (marked with the dative case, or with the infinitive, as in (1)), nor in relative past tense clauses (marked with the ablative case).

Equational, identificational, and attributive clauses are generally headed by nominals, with no copula verb. In these clauses, the nominal predicate and its subject typically agree in number, gender, and case (i.e., nominative). Such nominal clauses cannot contain an auxiliary.

(10) Naniyaga guji-nya ngarri-rna.
that.SG.II.NOM *mother*-II.NOM *my*-II.NOM
'That's my mother.'

Wang Li (1900–1986)

R J LaPolla, La Trobe University, Bundoora, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

Wang Li (Wang Liaoyi) was one of the three most prominent linguists in China in the 20th century. He was born August 10, 1900, in what is now Bobai County of the Guangxi Zhuang Autonomous Area. His family could not afford any more than a primary school education, but after studying on his own he was able to pass the entrance exam for the postgraduate program at Tsing Hua University in 1926, where he studied with Wang Guowei, Liang Qichao, Chen Yinke, and Chao Yuen Ren (*see* **Chao Yuen Ren (1892–1982)**). After Wang completed his thesis on Old Chinese grammar in 1927, Chao Yuen Ren encouraged him to go to the University of Paris to study. In Paris his focus changed from grammar to experimental phonetics, with his 1931 dissertation

being an analysis of the Bobai dialect of Chinese. Returning to China in 1932, he took up a position at Tsing Hua University. After the Japanese invasion in 1937, he followed the university to Changsha and then Kunming, but took a sabbatical in Vietnam from 1939 to 1940, studying Vietnamese and Sino-Vietnamese loanwords. In 1946 he went to Zhongshan University, where he founded the Linguistics Department, and moved to Lingnan University two years later. During the restructuring of universities in 1952, Wang moved back to Zhongshan University to be head of the Linguistics Department; in 1954 this department was merged with the Chinese Department of Beijing University, where he remained until his death in 1986.

After 1949, Wang was active politically, as a representative to the National People's Congress and the Beijing and National Political Consultative Congresses. He was also Deputy Chairman of the Chinese Language Reform Committee, an advisor to the National Language Work Committee, member of the Academy of Sciences, and Honorary President of the Chinese Linguistics Association and the Chinese Phonology Association.

Wang was a prolific writer; even during the war years he continued publishing. He wrote 40 books and over 200 academic articles, plus poetry, short literary pieces, and dozens of translations from French and other languages into Chinese. His linguistic work covers all aspects of linguistics: experimental phonetics, which he applied to the study of traditional Chinese philology and reconstruction; the grammar of Old Chinese and Modern Chinese and the changes in between; language standardization and education; and the structure of poetry. He was one of the first to systematically study Chinese grammar on its own terms, arguing that concepts from English grammar should not be blindly applied to the Chinese language. In Chinese traditional phonology and the historical reconstruction of Old Chinese, he found that one of the rhyme categories needed to be split to account for the rhyming patterns of the old texts, and argued, *contra* Bernard Karlgren, that each rhyming category should only have one main vowel and there should be some open syllables. He also argued that there should be only two tones in Old Chinese, with long and short syllables in the two tones giving rise to the later four-tone system.

Wang, NianSun (1744–1832)

B-C Kwok, Hong Kong, China

© 2006 Elsevier Ltd. All rights reserved.

Wang NianSun (1744–1832; also known as Wang Huaizu) is regarded as one of the greatest Chinese philologists of the Qing dynasty (1644–1911). He received his early education from Dai Zhen (1725–1777), who gave him a solid background in the field. Like his predecessors, Wang was a Confucian scholar intent on understanding the ancient texts, and this led to his interest in Chinese historical phonology and philology. He produced numerous annotations and emendations on classical texts. His masterpiece,

being an analysis of the Bobai dialect of Chinese. Returning to China in 1932, he took up a position at Tsing Hua University. After the Japanese invasion in 1937, he followed the university to Changsha and then Kunming, but took a sabbatical in Vietnam from 1939 to 1940, studying Vietnamese and Sino-Vietnamese loanwords. In 1946 he went to Zhongshan University, where he founded the Linguistics Department, and moved to Lingnan University two years later. During the restructuring of universities in 1952, Wang moved back to Zhongshan University to be head of the Linguistics Department; in 1954 this department was merged with the Chinese Department of Beijing University, where he remained until his death in 1986.

After 1949, Wang was active politically, as a representative to the National People's Congress and the Beijing and National Political Consultative Congresses. He was also Deputy Chairman of the Chinese Language Reform Committee, an advisor to the National Language Work Committee, member of the Academy of Sciences, and Honorary President of the Chinese Linguistics Association and the Chinese Phonology Association.

Wang was a prolific writer; even during the war years he continued publishing. He wrote 40 books and over 200 academic articles, plus poetry, short literary pieces, and dozens of translations from French and other languages into Chinese. Wang NianSun (1744–1832; also known as Wang Huaizu) is regarded as one of the greatest Chinese philologists of the Qing dynasty (1644–1911). He received his early education from Dai Zhen (1725–1777), who gave him a solid background in the field. Like his predecessors, Wang was a Confucian scholar intent on understanding the ancient texts, and this led to his interest in Chinese historical phonology and philology. He produced numerous annotations and emendations on classical texts. His masterpiece,

Guangya shuzheng (Annotations and evidence on *Guangya*), was the result of a ten-year effort.

Guangya is a dictionary compiled by Zhang Yi of the 3rd century. Wang's *Shuzheng* cannot simply be treated as an annotation. It also contains emendations and corrections of *Guangya*, often with examples from other documents to support his argument. His profound knowledge of Chinese phonology lead to the following breakthroughs:

1. In the preface of *Shuzheng*, Wang stated that words that sound the same or similar have related meanings. Thus, studies on the old meaning of words should be based upon their old sound, not on the meaning radicals of the Chinese characters, as had been the practice up to that time. Wang's theories brought us a better understanding of the nature of Chinese word families.
2. Wang was able to identify old phonetic uses of characters *(jiajie* in Chinese; using a character for one word for its sound value alone to represent another word) by examining their sounds. Many misinterpretations in classical texts were thus corrected.

Wang's theories in phonology were elaborated in his *Shijing qunjing Chuci yunpu* (*Manual of rhymes in the Shijing, other classical texts and Chuci*), *Jingyi shuwen* (*A description on the meaning of classical texts*), *Yu Li Fangbo shu* (*A letter to Li Fangbo*), and *Yu Jiang Jinsan shu* (*A letter to Jiang Jinsan*). He divided Old Chinese into 21 rhyme categories, a result that is almost identical to the works of his contemporaries Duan Yucai (*see* **Duan Yucai (1735–1815)**) and Jiang Yougao (?–1851). Interestingly enough, they worked independently but arrived at very similar conclusions. Wang's theories represented the peak of Qing phonological studies. Many modern scholars have followed the main body of Wang's system with only minor modifications.

Wang Niansun's elder son Yinzhi (1766–1834) also contributed to the field of Chinese philology. While following the principles set up by his father, Wang Yinzhi focused more on grammatical words. His *Jingzhuan shici* (*Explanations of words in classical texts*) is a pioneer work in the field.

War Rhetoric

T van Leeuwen, Cardiff University, Cardiff, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

With its massive conscript armies and unprecedented carnage, the First World War required greater support and greater sacrifices from the population than any previous war. As a result war propaganda grew in importance, and the then relatively new medium of the mass press played a crucial role in mobilizing public opinion in favor of the war. Soon after, the study of war propaganda, and of public opinion generally, became a new field in American political science. Harold Lasswell's *Propaganda techniques in the World War* (1927) is still a classic in the field. In this book Lasswell identified key propaganda strategies, such as the demonization of the enemy leader, the need to couch war propaganda in terms of defense, the exaggeration of atrocities, and the need to devise different justifications for different groups in the population on the basis of their different interests. All these strategies can still be seen at work in contemporary war rhetoric.

Lasswell was no linguist, and in subsequent years propaganda would primarily be studied by historians and political scientists, with relatively little systematic analysis of the linguistic means by which it was realized. The use of language in Nazi propaganda, with its vast set of bureaucratic terms and acronyms and its astounding euphemisms, such as *Sonderbehandlung* 'special treatment' for 'execution,' and *Endlösung* 'final solution' for 'the extermination of the Jews,' was an exception. A well-known example is the work of Victor Klemperer, a Jewish professor of linguistics in Dresden who, in 1933, was forced out of his job and forbidden to publish by the Nazis, and

Guangya shuzheng (Annotations and evidence on *Guangya*), was the result of a ten-year effort.

Guangya is a dictionary compiled by Zhang Yi of the 3rd century. Wang's *Shuzheng* cannot simply be treated as an annotation. It also contains emendations and corrections of *Guangya*, often with examples from other documents to support his argument. His profound knowledge of Chinese phonology lead to the following breakthroughs:

1. In the preface of *Shuzheng*, Wang stated that words that sound the same or similar have related meanings. Thus, studies on the old meaning of words should be based upon their old sound, not on the meaning radicals of the Chinese characters, as had been the practice up to that time. Wang's theories brought us a better understanding of the nature of Chinese word families.
2. Wang was able to identify old phonetic uses of characters *(jiajie* in Chinese; using a character for one word for its sound value alone to represent another word) by examining their sounds. Many misinterpretations in classical texts were thus corrected.

Wang's theories in phonology were elaborated in his *Shijing qunjing Chuci yunpu* (*Manual of rhymes in the Shijing, other classical texts and Chuci*), *Jingyi shuwen* (*A description on the meaning of classical texts*), *Yu Li Fangbo shu* (*A letter to Li Fangbo*), and *Yu Jiang Jinsan shu* (*A letter to Jiang Jinsan*). He divided Old Chinese into 21 rhyme categories, a result that is almost identical to the works of his contemporaries Duan Yucai (*see* **Duan Yucai (1735–1815)**) and Jiang Yougao (?–1851). Interestingly enough, they worked independently but arrived at very similar conclusions. Wang's theories represented the peak of Qing phonological studies. Many modern scholars have followed the main body of Wang's system with only minor modifications.

Wang Niansun's elder son Yinzhi (1766–1834) also contributed to the field of Chinese philology. While following the principles set up by his father, Wang Yinzhi focused more on grammatical words. His *Jingzhuan shici* (*Explanations of words in classical texts*) is a pioneer work in the field.

War Rhetoric

Introduction

With its massive conscript armies and unprecedented carnage, the First World War required greater support and greater sacrifices from the population than any previous war. As a result war propaganda grew in importance, and the then relatively new medium of the mass press played a crucial role in mobilizing public opinion in favor of the war. Soon after, the study of war propaganda, and of public opinion generally, became a new field in American political science. Harold Lasswell's *Propaganda techniques in the World War* (1927) is still a classic in the field. In this book Lasswell identified key propaganda strategies, such as the demonization of the enemy leader, the need to couch war propaganda in terms of defense, the exaggeration of atrocities, and the need to devise different justifications for different groups in the population on the basis of their different interests. All these strategies can still be seen at work in contemporary war rhetoric.

Lasswell was no linguist, and in subsequent years propaganda would primarily be studied by historians and political scientists, with relatively little systematic analysis of the linguistic means by which it was realized. The use of language in Nazi propaganda, with its vast set of bureaucratic terms and acronyms and its astounding euphemisms, such as *Sonderbehandlung* 'special treatment' for 'execution,' and *Endlösung* 'final solution' for 'the extermination of the Jews,' was an exception. A well-known example is the work of Victor Klemperer, a Jewish professor of linguistics in Dresden who, in 1933, was forced out of his job and forbidden to publish by the Nazis, and

who throughout the subsequent years recorded his observations of Nazi language, eventually publishing them as *The language of the Third Reich–LTI–Lingua Tertii Imperii: a philologist's notebook* (2000). More recent discussions of Nazi language include Wodak and De Cilla (1988) and Ehlich (1989). Several lexicons of Nazi language have appeared (e.g., Michael and Doerr, 2002).

Critical Linguistics

In Europe, linguistic analyses of war rhetoric reappeared from the 1970s onward, especially in relation to Cold War rhetoric and the nuclear arms debate, and, more recently, in relation to America's interventions in the Middle East and the so-called 'war on terror' that followed the events of September 11, 2001. This work formed part of the activities of the 'critical linguistics' movement that began in the mid–1970s at the University of East Anglia, and in the 1990s evolved into the broader movement of 'critical discourse analysis' (CDA). The analyses were written as immediate interventions in the debates of the moment and aimed at undermining the justifications of specific wars and aggressive policies in speeches by government leaders and in mainstream media. A key collection of critical linguistic essays on war rhetoric was Chilton (1985). CDA-oriented papers on war rhetoric have mainly appeared in journals such as *Discourse and Society*, *Critical Discourse Studies*, and the *Journal of Language and Politics*, which will publish a special issue in 2005 on this theme.

The critical linguists of the 1970s and 1980s took inspiration from the work of George Orwell, who had criticized political language in his 1946 essay 'Politics and the English Language' (2000) and in his description of 'Newspeak' in *Nineteen eighty-four* (quoted in Chilton, 1985: 45):

> The purpose of Newspeak was not only to provide a medium of expression for the worldview and mental habits proper to the devotees of Ingsoc [the dominant ideology], but to make all other modes of thought impossible. It was intended that when Newspeak had been adopted . . . a thought diverging from the principles of Ingsoc should be literally unthinkable, at least as far as thought is dependent on words.

Chilton made a similar though perhaps slightly diluted claim for 'Nukespeak' (ibid: 44):

> To coin the term Nukespeak is to make the claim that talk about nuclear weapons, nuclear war and nuclear politics is carried out by distinct words and phrases, and this in itself has important consequences for thought and action.

To analyze these words and phrases, critical linguists used a wide range of methods, including systemic-functional grammatical analysis (e.g., Moss, 1985), semantic field analysis and metaphor (e.g., Chilton, 1988), Greimasian semiotic analysis (e.g., Van Belle and Claes, 1985), Goffmanian frame analysis and Gricean conversation principles (e.g., Richardson, 1985), but by and large the critique was based on identifying linguistic manipulations (or 'transformations', e.g., Hodge, 1985), which were then interpreted as ideologically motivated distortions, in Chilton's words, on showing how the 'local organization of lexis and syntax . . . highlights certain meanings and obfuscates others' (1985: xiv). Some of these linguistic manipulations are relatively obvious and have also been commented on by many media commentators. These include euphemisms, such as the relatively neutral 'strike' for a nuclear attack, or to take a more recent one, 'collateral damage' for the death of innocent civilians; technical terms, especially acronyms (e.g., WMD for 'weapons of mass destruction'); and the names of weapons and military operations, e.g., the name of the MX missile in the Reagan era ('Peacekeeper') or the name of the bomb that destroyed Hiroshima ('Little Boy'). In his description of Newspeak ('War is Peace and Peace is War' was one of its slogans), Orwell had already identified these phenomena and pointed at the way they constitute 'doublespeak' – the dissolution of the oppositions without which debate about issues such as war and peace becomes impossible (see Orwell, quoted in Chilton, 1988: 80; cf. also Hodge, 1985: 136): 'Defenceless villages are bombarded from the air, the inhabitants driven out, the huts set on fire with incendiary bullets . . . this is called "pacification."' Other, less obvious local organizations of lexis and syntax included grammatical agency, nominalization, and metaphor. In 'call to arms' speeches, for instance, the ascription of agency fluctuates between the addressed audience ('we'), the nation ('America,' 'this country'), and the moral cause that justifies war ('Western commitment to democracy'), thus conflating the three, while the actions ascribed to these agents tend to be referred to in abstract terms, as in Bush's speech of March 16, 2003 (http://www.whitehouse.gov/news/re/cases/2003/03) ("We work towards a great cause, and that is peace and security in this world"). The actions of the enemy tend to be more concrete and are ascribed to a personified and demonized enemy, as in the same speech ("The dictator of Iraq and his weapons of mass destruction are a threat to the security of free nations"). This then creates an us-them contrast. The nominalization of war actions and the use of agentless passive constructions obscures agency, as in the *Times'* headlines at the time of the

Hiroshima and Nagasaki bombings of April 7 and 10, 1945: 'Rain of Ruin from the Air' and 'Second City Hit.' Metaphors can make new and unprecedented events appear familiar, natural, and acceptable, as in the now increasingly common descriptions of war as a 'job' and as 'business.' Chilton (1988: 72) quotes an example from the *Daily Mail* of May 3, 1982: "An Argentine submarine appears to be hit. All this means is that the British forces are getting on with the job they were sent down to the South Atlantic to do, namely to remove the Argentines." The importance of metaphor for our understanding of the world we live in has been powerfully argued by Lakoff and Johnson (1981); at the time of the first Gulf War, Lakoff wrote a paper on metaphor and war (1991), which he published on the Internet to avoid delay in publication and make it more widely available.

Critical Discourse Analysis

Already in the mid-1980s, critical linguists also began to analyze war rhetoric in terms of discourses, 'belief systems,' for example in relation to the long-lasting antinuclear demonstration by women at Greenham Common (Fowler and Marshall, 1985). Here the focus was not on words and phrases but on particular complexes of ideas, such as that women are less rational than men, should confine themselves to domestic and maternal tasks, and so on. Such belief systems then manifested themselves through a range of lexical and syntactic means and in a range of contexts, for example through the use of terms such as 'peace hysteria' and 'protesting peace mums' in the popular press. Chilton (1988) related this to work on scripts and schemas in cognitive linguistics and artificial intelligence (e.g., Abelson, 1973, who had used the 'Cold War script' as one of his examples), pointing out that metaphors can often trigger whole complexes of ideas without referring to them in explicit and detailed ways.

More recent work in critical discourse analysis has increasingly moved in the direction of identifying broad discursive strategies, focusing especially on the 'legitimation' of war (at other times the term 'justification' is used). Several articles of this kind can be found in a special issue of the journal *Discourse and Society* (*15*: 2–3) on the events of September 11, 2001, and their aftermath. Graham *et al*. (2004), for instance, point at the remarkable consistency of the strategies used in call to war speeches over the past 1000 years. Studying a hundred such speeches, they found that all (1) refer to an ultimate moral force to legitimate the war (although the nature of this moral force evolved from 'God,' to 'God and Country,' and then to 'Country' or 'People' alone); (2) embed the discourse in the history and culture that binds 'us,' the addressed audience that must be rallied behind the war, together; (3) construct the enemy as an evil other; and (4) provide unifying constructs for the people addressed. Lazar and Lazar (2004) deal specifically with 'enemy construction' and discuss strategies of 'criminalization,' 'orientalization,' and 'vilification.' Although they specify linguistic realizations of these categories in some cases (for instance, 'criminalization' is realized by the use of criminal vocabulary and 'overlexicalization'), in other cases the realizations are semantic categories (for instance, 'orientalization' can be realized by 'moral degeneracy,' 'bellicosity,' and 'duplicity'). In short, there has been a gradual move from an emphasis on 'local' lexical and syntactic features to an emphasis on overall rhetorical strategies and discourses (in the sense of belief systems). However, in most cases the argumentation still rests primarily on the use of discourse analytical methods. Relatively little connection is made with literature on the specific wars and conflicts discussed, or with literature from other fields, such as media studies, where less attention is paid to language but more to the context, e.g., to documenting forms of wartime media censorship (see, e.g., Schlesinger *et al*., 1983, which appeared roughly at the same time as Chilton, 1985).

Rhetoric

The American approach to war rhetoric has by and large based itself on traditional rhetorical analysis, with explicit reference to Aristotle and the classic rhetoricians, and often also with reference to the work of Kenneth Burke (e.g., 1969), who saw rhetoric as language's essential function of inducing social cooperation. This work is closely linked to the American tradition of public opinion and mass communication research that started in the 1920s with the work of Lasswell, Lippman, and others, and has never lost sight of rhetoric's time-honored connection between political speechmaking and political action, a connection that critical linguists had to regain after having been trained in the formal and decontextualized linguistics of the 1950s and 1960s. American journals such as *Communication Monographs* and *Quarterly Journal of Speech* have been publishing articles on war rhetoric for a long time (e.g., Brockriede and Scott, 1969 Medhurst *et al*., 1982), and while war rhetoric has not become an area of specialization among critical discourse analysts (Chilton is perhaps the single exception), in America war rhetoric did become a specialized area of scholarship (see, e.g., Medhurst *et al*., 1997). A glance at the Internet soon shows in just how many

American universities courses on war rhetoric are taught, with syllabuses that are sometimes preceded by the warning that controversial issues will be on the agenda. Textbooks and syllabuses use a variety of methods for the analysis of war rhetoric, including strategies, from the classic Aristotelian notions of 'ethos' (establishing the credibility and trustworthiness of the speaker), 'pathos' (appealing to the emotions of the audience), and 'logos' (providing evidence to back up what is proposed) to strategies such as 'evasion' and 'diversion,' as well as specific rhetorical techniques, including euphemism, jargon, and metaphor, as well as, for instance, repetition and specific techniques for the analysis of argumentation and the discovery of fallacies.

Conclusion

The European and American approaches to war rhetoric are motivated by the same concern: a concern for maintaining the reasoned and critical forms of debate that have been fundamental to democracy since the days of Plato and Aristotle. More recently they have also grown more closely together in terms of their methods. American work has started to incorporate notions such as 'genre' and 'intertextuality,' and European work has become more interdisciplinary, linking up with historical and politicological approaches to war propaganda and with the specific histories of the discourses that are being analyzed and critiqued, and paying attention to nonlinguistic forms of war rhetoric, realizing, for instance, that images can play a particularly important role in strategies such as the demonization of enemies and the exaggeration of atrocities. And while most analyses have focused on political speeches and media reports and commentaries, there is now also an increasing realization of the importance of entertainment media in war propaganda, something which had already been noted in the context of media studies (see Schlesinger *et al.*, 1983). The link between entertainment and propaganda goes back at least as far as the 1930s, when Goebbels (1948: 122) wrote that 'argument is no longer effective' and looked toward popular song, humor, and movies as key media of propaganda: "With films we can make politics too. It is a good expedient in the struggle for the soul of our people" (quoted in Bramstedt, 1965: 278). Today there is close cooperation between the Pentagon and the producers of the computer war games and Hollywood war movies (see Machin and Van Leeuwen, in press) that disseminate demonized images of the new 'terrorist' enemy and allow people to identify with American heroes.

In the current political climate it is clearly important that critical work on war rhetoric continues and that it is written accessibly and disseminated effectively, not least so that it can feed into the work of the journalists and media commentators who continue to write critically about the war rhetoric of today's world leaders; a glance at the Internet shows that many still do.

Ward, Ida Caroline (1880–1950)

B S Collins, Leiden University, Leiden, The Netherlands
I M Mees, Copenhagen Business School, Copenhagen, Denmark

© 2006 Elsevier Ltd. All rights reserved.

Ida Caroline Ward, one of the leading Africanists of the 20th century, was born in Bradford, England, on October 4, 1880, the eighth child of a prosperous Yorkshire wool merchant. She was educated at the University of Durham, and then embarked on a long and successful career in school teaching. When in her thirties, she began to interest herself in linguistics, attending classes at Daniel Jones's newly established department of phonetics at University College London, Jones offered her a full-time post in 1919 at UCL, where initially she specialized in English phonetics and speech pathology. Her early books, S*peech defects: their nature and cure* (1923), *A handbook of English intonation* (1926, written with her departmental colleague Lilias Armstrong), and the popular *Phonetics of English* (1929), reflect these enthusiasms.

Ward soon began to focus more on the languages of West Africa and in 1932 moved over to London University's School of Oriental Studies (later renamed School of Oriental and African Studies), where she could indulge this interest to the full. With Diedrich Westermann, she wrote the wide-ranging survey *Practical phonetics for students of African languages* (1933) and in the same year produced her pioneering *Phonetic and tonal structure of Efik*; for the latter she was awarded a D.Lit. from London University. Further groundbreaking research on tone systems gave rise to a series of publications on West African languages, in particular her *Introduction to the Ibo language* (1936), which also explored vowel harmony. Her final major work in this area was the *Introduction to the Yoruba language*, published posthumously in 1952.

Ida Ward is notable not only for the accuracy and meticulousness of her empirical research but also for the lucid exposition of theoretical principles of tonal analysis, which she developed at a point when this study was in its infancy. She carried out all her work through direct contact with native-speaker informants, undertaking long linguistic field trips to West Africa even in the hazardous travel conditions of World War II.

Ida Ward was arguably the most brilliant of Daniel Jones's many talented pupils, and her contribution laid the foundations for much subsequent research into African tone languages. In 1937 she established a department of West African languages in SOAS with herself at the head, where in 1944 she was appointed to a chair. She was unquestionably one of the most important driving forces that made London University in her lifetime the chief center of research into African linguistics. She retired in 1948, but continued to work right up to her death in 1949.

Further groundbreaking research on tone systems gave rise to a series of publications on West African languages, in particular her *Introduction to the Ibo language* (1936), which also explored vowel harmony. Her final major work in this area was the *Introduction to the Yoruba language*, published posthumously in 1952.

Ida Ward is notable not only for the accuracy and meticulousness of her empirical research but also for the lucid exposition of theoretical principles of tonal analysis, which she developed at a point when this study was in its infancy. She carried out all her work through direct contact with native-speaker informants, undertaking long linguistic field trips to West Africa even in the hazardous travel conditions of World War II.

Ida Ward was arguably the most brilliant of Daniel Jones's many talented pupils, and her contribution laid the foundations for much subsequent research into African tone languages. In 1937 she established a department of West African languages in SOAS with herself at the head, where in 1944 she was appointed to a chair. She was unquestionably one of the most important driving forces that made London University in her lifetime the chief center of research into African linguistics. She retired in 1948, but continued to work right up to her death in 1949.

Warlpiri

R Hoogenraad, Alice Springs, NT, Australia

© 2006 Elsevier Ltd. All rights reserved.

Warlpiri is a Pama-Nyungan language of the Ngumbin-Yapa subgroup (see McConvell and Laughren, 2004) spoken by some 3000 *Yapa* 'people' (typically Warlpiri people). The Warlpiri heartland is the Tanami Desert to the northwest of Alice Springs in Australia's Northern Territory, but the Warlpiri-speaking population now lives mainly in four communities around the margins of this area: Lajamanu, Nyirrpi, Yurntumu, and Wirliyajarrayi. There are also sizable populations in Katherine, Tennant Creek and Alice Springs, and in Aboriginal communities around the Warlpiri area. Warlpiri is also used over a larger area as a lingua franca – possibly up to 1000 Aboriginal people speak Warlpiri as a second language.

Warlpiri had seven dialects, which are now being reduced to four communalects: Yurntumu/Nyirrpi, Lajamanu, Wirliyajarrayi, and Wakirti Warlpiri (Alekarenge and Tennant Creek).

All the neighboring languages belong to the Pama-Nyungan family: Ngumbin-Yapa subgroup (Warlpiri, Ngardi, Jaru, Nyininy, Gurindji, Mudburra, Warlmanpa), Warumungu, Western Desert group (Pintupi Luritja, Pintupi, Kukatja), Arandic Group (Alyawarr, Kaytetye, Central Anmatyerr). Though there are significant differences between them, they share many of their core structural and sociolinguistic features.

Warlpiri Grammar

Ken Hale was Warlpiri's 'recording angel,' starting in 1959 (see the bibliography in Simpson *et al*., 2001). There is a learner's guide (Laughren *et al*., 1996), and good overviews are provided by Nash (1986), Hale *et al*. (1995), Simpson (1991), and the collection of papers in Swartz (1982a).

A Warlpiri encyclopedic dictionary is in preparation: the database currently has over 9500 entries. Hale (1995) is a simple dictionary with nearly 2000 entries, and has an appendix with a concise grammatical inventory (as has Hale *et al*., 1995).

Phonology

Table 1 shows the consonant phonemes in the standard orthography in use since 1974. The contrast between postalveolar stop *rt* and flap *rd* is only allophonic in eastern dialects: Wirliyajarrayi and Wakirti Warlpiri.

There are three vowels, i, u, and a. High vowels *u* and *i* harmonize with adjacent high vowels across morpheme boundaries: progressive in nominals, *wati-ngki* man-ERG, *kurdu-ngku* child-ERG, but regressive in verbs, *kipi-rni* winnow-PRES, *kupu-rnu* winnow-PAST. The low vowel *a* blocks vowel harmony: *kirlilkirlilpa-rlu* galah-ERG; *yirra-rni* put-PRES,

Table 1 Warlpiri consonants

	Peripheral		*Coronal*		
	Bilabial	*Velar*	*Lamino-palatal*	*Apico-postalveolar (retroflex)*	*Apico-alveolar*

Warlpiri

R Hoogenraad, Alice Springs, NT, Australia

© 2006 Elsevier Ltd. All rights reserved.

Warlpiri is a Pama-Nyungan language of the Ngumbin-Yapa subgroup (see McConvell and Laughren, 2004) spoken by some 3000 *Yapa* 'people' (typically Warlpiri people). The Warlpiri heartland is the Tanami Desert to the northwest of Alice Springs in Australia's Northern Territory, but the Warlpiri-speaking population now lives mainly in four communities around the margins of this area: Lajamanu, Nyirrpi, Yurntumu, and Wirliyajarrayi. There are also sizable populations in Katherine, Tennant Creek and Alice Springs, and in Aboriginal communities around the Warlpiri area. Warlpiri is also used over a larger area as a lingua franca – possibly up to 1000 Aboriginal people speak Warlpiri as a second language.

Warlpiri had seven dialects, which are now being reduced to four communalects: Yurntumu/Nyirrpi, Lajamanu, Wirliyajarrayi, and Wakirti Warlpiri (Alekarenge and Tennant Creek).

All the neighboring languages belong to the Pama-Nyungan family: Ngumbin-Yapa subgroup (Warlpiri, Ngardi, Jaru, Nyininy, Gurindji, Mudburra, Warlmanpa), Warumungu, Western Desert group (Pintupi Luritja, Pintupi, Kukatja), Arandic Group (Alyawarr, Kaytetye, Central Anmatyerr). Though there are significant differences between them, they share many of their core structural and sociolinguistic features.

Warlpiri Grammar

Ken Hale was Warlpiri's 'recording angel,' starting in 1959 (see the bibliography in Simpson *et al*., 2001). There is a learner's guide (Laughren *et al*., 1996), and good overviews are provided by Nash (1986), Hale *et al*. (1995), Simpson (1991), and the collection of papers in Swartz (1982a).

A Warlpiri encyclopedic dictionary is in preparation: the database currently has over 9500 entries. Hale (1995) is a simple dictionary with nearly 2000 entries, and has an appendix with a concise grammatical inventory (as has Hale *et al*., 1995).

Phonology

Table 1 shows the consonant phonemes in the standard orthography in use since 1974. The contrast between postalveolar stop *rt* and flap *rd* is only allophonic in eastern dialects: Wirliyajarrayi and Wakirti Warlpiri.

There are three vowels, i, u, and a. High vowels *u* and *i* harmonize with adjacent high vowels across morpheme boundaries: progressive in nominals, *wati-ngki* man-ERG, *kurdu-ngku* child-ERG, but regressive in verbs, *kipi-rni* winnow-PRES, *kupu-rnu* winnow-PAST. The low vowel *a* blocks vowel harmony: *kirlilkirlilpa-rlu* galah-ERG; *yirra-rni* put-PRES,

Table 1 Warlpiri consonants

	Peripheral		*Coronal*		
	Bilabial	*Velar*	*Lamino-palatal*	*Apico-postalveolar (retroflex)*	*Apico-alveolar*
Stop	*p*	*k*	*j*	*rt*	*t*
Nasal	*m*	*ng*	*ny*	*rn*	*n*
Lateral			*ly*	*rl*	*l*
Flap/tap				*rd*	*rr*
Glide	*w*		*y*		*r*

yirra-rnu put-PAST. A syllable may have one 'short' vowel or a sequence of two identical vowels, e.g., *ngurrpa* 'ignorant of,' *nguurrpa* 'windpipe.'

The Word

Warlpiri words must have at least two vowels, in the same or sequential syllables, with an initial consonant and a final vowel and stress on the first syllable. The alveolar/postalveolar distinction (see Table 1) is neutralized word initially. The laminopalatal *ly* only occurs following a vowel.

There is a mora (or vowel) counting rule that determines the choice between the two forms of the locative (*-ngka* vs. *-rla*) and ergative (*-ngku*∼*i* vs. *-rlu*∼*i*), with minimal words hosting the velar allomorph, e.g., *ngurrpa-ngku* vs. *nguurrpa-rlu* (Hale, 1995: Appendix).

Clauses

Warlpiri has a classical nonconfigurational clause structure, with 'free' word order, discontinuous constituents, and a high reliance on zero anaphora (Hale, 1983; Hale *et al*., 1995; Swartz, 1991). It has verbal and nominal (i.e., verbless) clauses. The nominal clause can be rendered as a verbal clause using one of the stance verbs as copula (see Table 2).

Ngapa ngurrju. Ngapa-ka karri-mi ngurrju.
water good *water*-AUX *vertical.(stand)*-PRES *good*
'The water is good.'

The verbal clause consists of an obligatory verb and associated auxiliary complex, and a number of optional case-marked nominal constituents, as well as adverbial enclitics and particles with clausal or subclausal scope (Laughren, 1982a). Dependent and nonfinite subordinate clause types are discussed in Hale (1976) and Hale *et al*. (1995).

Table 2 Warlpiri stance verbs/copula (verb 'to be')

Neutral	*Vertical*	*Horizontal*	*Humped*
nyinami 'sit, stay'	*karrimi* 'stand'	*ngunami* 'lie'	*parntarrimi* 'crouch'

Verbs

There are 170 simple verb stems, which inflect for tense and mood in five conjugations. Past, nonpast and irrealis verbs co-occur with aspect auxiliaries (see Table 3), while the imperative, infinitive, future, and presentational forms do not. Derivational morphology creates a nomic or agentive/instrumental noun from verbs (Hale, 1995), and inceptive and iterative verb forms which inflect for tense and mood, e.g., *payirni-njina-* 'go and ask' vs. *payirni-njina-na-*'go about asking.'

Verbs are fixed in one of five transitivity patterns specifying syntactic case arrays: intransitive, bi-intransitive, middle, transitive, and bi-transitive (Swartz, 1982b).

The inchoative *-jarri-* and the transitivizer *-ma-* are two very productive verb formatives with nominal stems. They form interrogative verbs: *Nyarrpa-jarrija?* 'What did (he) do?' and *Nyarrpa-manu?* 'What did (he) do to (it)?'

Verbal meanings are further expanded by a large open noninflecting category termed preverb, particularly with the eight monosyllabic verb roots (Nash, 1982): ***nyanyi*** 'seeing,' ***purda-nyanyi*** 'hearing,' ***parnti-nyanyi*** 'smell.' Nominals, e.g., *jarda* 'sleep, asleep,' can act as preverbs; *jarda-ngunami* 'asleep-lying, sleeping.'

Nominals

Nominals make up the largest grammatical class, and include substantives (nouns) and descriptive terms (adjectives), free pronouns, the deictics and determiners, question words, etc. In verbal clauses they are optional. Nominals host number-marking suffixes

Table 3 The Warlpiri auxiliary complex

Aspect and tense					
-Ø- (i.e., nothing)			*-ka-*	*-lpa-*	
Perfective			*Imperfective*		
Nonpast	*Past*	*Irrealis*	*Nonpast*	*Past*	*Irrealis*
Immediate probability ngarri**rni** 'about to tell, may tell'	Completed action ngarru**rnu** 'has told, told'	Past possibility, probability ngarri**karla** 'would/should have told'	Happening; habitually happens **-ka** ngarri**rni** 'is telling, tells'	Action in progress in past **-lpa** ngarru**rnu** 'was telling'	Possibility, probability **-lpa** ngarri**karla** 'would/should tell'

Table 4 Warlpiri grammatical number

	Singular (one)	*Dual (a pair)*	*Paucal (several)*		*Plural (more)*
Nouns, interrogatives, adjectives	*-Ø*	*-jarra*	*-patu*		*-Ø*
Definite deictic and determiners	*-Ø*	*-jarra*	*-patu*		*-rra*
Indefinite determiners	*jinta*	*jirrama*	*marnkurrpa*		*panu*
3rd Person subject pronominal clitics	*-Ø*	*-pala*		*-li∼lu*	
3rd Person object pronominal clitics	*-Ø*	*-palangu*		*-jana*	

Table 5 Warlpiri spatial cases

-ngka∼rla	locative 'at, on, in'	*-kurra* allative 'to, up to'	*-ngurlu*	elative 'from'
-wana	'along, around'		*-jangka*	'from' origin, cause

(see Table 4), followed by a range of syntactic and semantic case suffixes (Hale *et al.*, 1995).

The three syntactic cases are in an ergative system. The ergative, *-ngku∼i* or *-rlu∼i*, marks the subject (agent) of a transitive verb. The absolutive, *-Ø* (zero), marks the subject of an intransitive verb and the object of a transitive verb. The dative, *-ku∼i*, marks indirect object and some oblique functions. There are a number of spatial cases, listed in Table 5, as well as an alienable possessive case. A grammatical case may suffix to a stem containing a semantic case (see Simpson, 1991).

Auxiliary Complex

The auxiliary complex is in the Wackernagel position, i.e., after the first constituent of the clause. The auxiliary complex comprises:

- an optional finite complementizer (Hale *et al.*, 1995)
- an aspect marker, which in concert with the verb tense specifies the temporal and aspectual meaning of the clause (Table 3)
- up to three pronominal clitics marking subject and nonsubject functions (Hale, 1973, 1982).

There is a systematic mapping of the syntactic case array specified by the verb – in an ergative system – onto the auxiliary pronominal clitics – in a subject-object system – described from different perspectives by Swartz (1982b) and Hale (1982).

The free pronouns and the pronominal clitics mark person and number (Table 4). Third person singular subject and direct object is unmarked. A clause can be very minimal, without any overt nominals or auxiliary morphemes, or it can be expanded with case-marked nominals, etc.

Jarnturnu.
'He trimmed it.'

can be expanded to:

Wati-ngki-Ø-Ø-Ø karli-Ø jarntu-rnu.
man-ERG-PERF-*3rd.sing*.SUBJ-*3rd.sing*.OBJ *boomerang*-ABS *trim*-PAST
'The man trimmed the boomerang.'

Expanding this, and changing the participants and aspect to show additional possibilities:

Ngajarra-ku kula-lpa-Ø-jarrangku-rla karli-Ø jarntu-rnu wati-ngki
1st.exl.dual-DAT NEG.COMP-IMPERF-*3rd.sing*.SUBJ-*1st.exl.dual*.-DAT *boomerang*-ABS *trim*-PAST *man*-ERG
'Us two (excluding you) was not for whom the man was trimming the boomerang.'

Meaning, Context, and Registers

I now discuss briefly some Warlpiri cultural preoccupations – with land, social relationships, and proper behavior – that are reflected in the language.

Tables 5–7 shows some of the ways in which spatial orientation and direction is encoded in the language. For instance, there is a rich set of deictics encoding distance, visibility, and definiteness, and the choice of copula is determined by the perceived orientation of the subject (see Table 2). In addition, there is a system of absolute three-dimensional spatial reference based on the four compass directions and up and down. The directional suffixes in Table 7 and additional suffixes create a rich system of spatial reference (Laughren, 1978).

Although Warlpiri had no counting system, Table 4 shows that it marks grammatical number on all nominals and references it in the pronominal clitics. There is a particular emphasis on pairing, reflected in the obligatory marking of dual, and the dual indefinite determiner.

There is also a preoccupation with relationships: the kin terminology allows any Yapa to be referenced as a relation, with higher order groupings into patrilineal, matrilineal, and generation moieties. There is

Table 6 Warlpiri spatial location and orientation: deictics

	Definite		*Indefinite*
	Location certain	*Not visible*	*Location uncertain*
Close	*nyampu* 'this, here'	*yalarnimpi* 'this one not visible'	*mirnimpi* 'somewhere here'
Nearby	*yalumpu* 'that, there'	*yalarni* 'that one not visible'	*mirni* 'somewhere there'
Further	*yali* 'yon, yonder'	*(yalarnimpayi?)* 'yonder not visible'	*mirnimpayi* 'somewhere yonder'
Distant	*yinya* 'far yonder'	*yalarnirra* 'that one far off out of sight'	*mirnirra* 'far away, a long way away'

Table 7 Warlpiri direction of action relative to speaker, suffixed to the inflected verb

Centripital	*Centrifugal*	*Perpendicular*
+*rni*~*rnu* 'towards (hither)'	+*rra* 'away (thither)'	+*mpa* 'across'

also a sociocentric system of eight subsections or 'skin names.'

Pairing shows up again in an extensive set of tri-relational kin terms, which allow any pair of people to be referenced as a triangulation of the relationship between the speaker and each of the pair, and the relationship between the pair (Laughren, 1982b), e.g., *makurnta-rlangu*, the relationship between one's brother-in-law and mother, who stand in the avoidance relationship of mother-in-law/son-in-law to each other (*kurnta* 'shame, proper behavior'). Relationship to land is also registered in the kinship system.

Warlpiri has respect registers, characterized by obliqueness, used when speaking about or to relations and ritual associates in avoidance or respect relationships (Laughren, 2001). *Rdaka-rdaka* 'Hand Talk' is a sign language used when speaking is inappropriate, especially by bereaved widows and mothers in the *jilimi* 'single women's camp' (Kendon, 1988). Baby Talk is used to talk to babies, incrementally building up the phonological, grammatical, and semantic features of Warlpiri for them as they develop (Laughren, 1984).

All these registers are characterized by hyperpolysemy and a systematic reduction in distinctions, giving us an insight into the organization of Warlpiri semantics, grammar, and phonology.

Wartburg, Walther von (1888–1971)

G Price

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 9, pp. 4964–4965, © 1994, Elsevier Ltd.

Walther von Wartburg was born on May 18, 1888 in Riedholz, Switzerland. He studied at the universities of Bern, Zürich, and Florence and then spent a year (1911–12) in Paris where he attended Gilliéron's seminars (*see* **Gilliéron, Jules (1854–1926)**) on linguistic geography at the Ecole des hautes études, an experience that was to prove fruitful particularly in that it led him to disagree with many of Gilliéron's views on the nature of language. After some years as a schoolmaster, he was appointed to his first university post at Lausanne in 1928, and was later to occupy chairs at the Universities of Leipzig (1929–1939) and Basle (1940 until his retirement in 1959). The first fascicle of his monumental French etymological dictionary, the *Französisches etymologisches Wörterbuch*, which is unrivaled in the field of any other language, appeared in 1922 and by 1928 the first volume was complete. Despite difficulties (some of them brought about by World War II and the problems of the postwar period) that necessitated a number of changes both of publisher and of place of publication, twenty volumes appeared before his death and others (including a complete reworking of the three prewar volumes) are in progress. Each article provides a wealth of information and examples not only from written French and Occitan of all periods but also from patois from the whole Gallo–Romance area, together with abundant bibliographical references. He had helpers, but Baldinger estimates that 85% of the text of vols. I–XIV, representing over 11 000 printed pages, is due to Wartburg himself. Meanwhile, he was also producing a succession of highly regarded books including (among many others) a bibliography of Gallo–Romance patois dictionaries (1934; new edition in collaboration with H.-E. Keller and R. Geuljans 1969), a history of the French language (1934, with nine further editions), and an influential if controversial account of the reasons (as he saw them) for the linguistic break-up of the Romance-speaking area. In 1947 he founded, as a branch of the German Academy of Sciences at Berlin, the Institute for Romance Linguistics whose publications he thereafter edited. His other wide-ranging editorial activities included (1935–1947) the *Zeitschrift für romanische Philologie* and its associated monographs. He died in Basle on August 15, 1971.

Walther von Wartburg was born on May 18, 1888 in Riedholz, Switzerland. He studied at the universities of Bern, Zürich, and Florence and then spent a year (1911–12) in Paris where he attended Gilliéron's seminars (*see* **Gilliéron, Jules (1854–1926)**) on linguistic geography at the Ecole des hautes études, an experience that was to prove fruitful particularly in that it led him to disagree with many of Gilliéron's views on the nature of language. After some years as a schoolmaster, he was appointed to his first university post at Lausanne in 1928, and was later to occupy chairs at the Universities of Leipzig (1929–1939) and Basle (1940 until his retirement in 1959). The first fascicle of his monumental French etymological dictionary, the *Französisches etymologisches Wörterbuch*, which is unrivaled in the field of any other language, appeared in 1922 and by 1928 the first volume was complete. Despite difficulties (some of them brought about by World War II and the problems of the postwar period) that necessitated a number of changes both of publisher and of place of publication, twenty volumes appeared before his death and others (including a complete reworking of the three prewar volumes) are in progress. Each article provides a wealth of information and examples not only from written French and Occitan of all periods but also from patois from the whole Gallo–Romance area, together with abundant bibliographical references. He had helpers, but Baldinger estimates that 85% of the text of vols. I–XIV, representing over 11 000 printed pages, is due to Wartburg himself. Meanwhile, he was also producing a succession of highly regarded books including (among many others) a bibliography of Gallo–Romance patois dictionaries (1934; new edition in collaboration with H.-E. Keller and R. Geuljans 1969), a history of the French language (1934, with nine further editions), and an influential if controversial account of the reasons (as he saw them) for the linguistic break-up of the Romance-speaking area. In 1947 he founded, as a branch of the German Academy of Sciences at Berlin, the Institute for Romance Linguistics whose publications he thereafter edited. His other wide-ranging editorial activities included (1935–1947) the *Zeitschrift für romanische Philologie* and its associated monographs. He died in Basle on August 15, 1971.

Watanabe, Shoichi (b. 1930)

M Miyawaki, Senshu University, Kanagawa, Japan

© 2006 Elsevier Ltd. All rights reserved.

Shoichi Watanabe, an eminent English philologist, was born in Tsuruoka, Yamagata Prefecture, Japan, on October 15, 1930. In 1949 he enrolled in the Department of English Literature, Sophia University, Tokyo, from where he proceeded to the Graduate Division of Western Culture Studies in 1953. After completing his M.A. thesis on Ben Jonson's English grammar (1640) in 1955, he went to Münster University, Germany, where he continued his study of the beginnings of English grammar writing under Karl Schneider, a distinguished runologist and philologist. In 1958 Watanabe obtained a Dr.Phil. *magna cum laude*, and then went to Oxford University to do postdoctoral research under E. J. Dobson.

In 1960 Watanabe was appointed a Lecturer in the Department of English Literature, Sophia University. He was promoted to Associate Professor in 1964 and to Professor in 1971. From 1968 to 1969 he gave lectures at six U.S. universities as a visiting professor with the support of a Fulbright-Hayes grant. In 1994 he was awarded a Dr.Phil.h.c. by Münster University "because of eminent academic contributions." He retired from Sophia University in 2001, and has been a Professor Emeritus since then. Currently, he is the President of the Philological Society of Japan and the President of the Japan Association of Bibliophiles.

Of Watanabe's numerous achievements, only a limited selection can be mentioned. His doctoral dissertation (1958; Japanese edition, 1965) is a thorough study of the early modern English grammars that demonstrates that they are far more dependent on medieval Latin grammars than had previously been thought, redressing the view of Otto Funke, who had emphasized the ancient and Humanist tradition. Watanabe completed this study at a time when there was not a single book on this subject in the English-speaking countries. *A history of English linguistics* (1975) is the most exhaustive investigation of grammatical and orthoepical theories before 1800. The coverage has been extended to include Generative Grammar in *Do you know English grammar?* (2003). *A history of the National Studies in England* (1990) propounds the hitherto unknown notion of 'the National Studies in Tudor England,' focusing on John Leland and Matthew Parker, who strove to identify the origins of their nation and religion through antiquarian studies. In celebration of Watanabe's retirement in 2001, his shorter writings were collected in two volumes and a massive catalogue of his splendid collection of philological books was published. His collection has been extolled by Dr. Christopher de Hamel, Librarian, Parker Library, Corpus Christi College, Cambridge, as "far more comprehensive than any private library known to me in England."

Web Searching

R Baeza-Yates and C Castillo, Center for Web Research, University of Chile, Santiago, Chile

© 2006 Elsevier Ltd. All rights reserved.

Introduction

A Web search engine takes a user need, usually stated in the form of a few key words, and returns a list of Web pages that can be considered relevant for the given key words. These Web pages are a short list of usually a few hundred items selected from a vast repository of billions of pages.

The 'easy' part of Web searching is to find which documents on the Web are related to a given query, because most queries are very broad, and there are thousands of pages relevant to most basic concepts. The hard part of Web searching is to rank those documents by relevance and select the top 10, say, to show the first result page to the user.

Although there was an important body of information retrieval algorithms and techniques published before the invention of the World Wide Web, there are unique characteristics of this new medium that made those techniques unsuitable or insufficient for Web searching.

> 'Information retrieval algorithms were developed for relatively small and coherent collections such as newspaper articles or book catalogs in a (physical) library. The Web, on the other hand, is massive, much less coherent, changes more rapidly, and is spread over geographically distributed computers…' (Arasu *et al.*, 2001)

The Web can be considered as divided into two parts, the 'closed Web' and the 'open Web' (Brooks, 2003). The 'closed Web' comprises a few high-quality controlled collections in which a search engine can fully trust. The 'open Web' includes the vast majority of Web pages, which lack an authority asserting their quality. In the open Web, traditional information-retrieval techniques, concepts, and methods are challenged.

To partly overcome this problem, hyperlinks between pages can be used in the same way as citations can be used in academic literature to find the most important papers in an area. Link analysis techniques can be used to exploit hyperlinks and extract useful information from them.

However, one of the main challenges that the open Web poses to search engines is 'search engine spamming', i.e., malicious attempts to get an undeserved high ranking in the list of results. This has created a whole branch of research called 'adversarial information retrieval' that deals with retrieving information from collections in which a subset of the collection has been manipulated to influence the outcome of ranking algorithms.

In the next sections, we present the main issues related to indexing, searching, ranking, and crawling the Web. We end with a section on the characteristics with the Web and another on research issues. Because of space restrictions, our coverage of details and bibliography is by no means complete. For further details on Web retrieval, we recommend Baeza-Yates and Ribeiro-Neto (1999).

Indexing and Querying Web Pages

The Web search process has two main parts: off-line and online.

The off-line part is executed periodically by the search engine, and consists in downloading a subset of the Web to build a collection of pages, which is then transformed into a searchable index.

The online part is executed every time a user query is executed and uses the index to select some candidate documents that are sorted according to an estimation on how relevant they are for the user's need. This process is depicted in Figure 1.

Web pages come in many different formats such as plain text, HTML pages, PDF documents, and other proprietary formats. The first stage for indexing Web pages is to extract a standard logical view from the documents. The most frequently used logical view for documents in search engines is the 'bag-of-words' model, in which each document is seen only as an unordered set of words. In modern Web search engines, this view is extended with extra information concerning word frequencies and text formatting attributes, as well as meta-information about Web pages including embedded descriptions and explicit key words in the HTML markup.

There are several text normalization operations (Baeza-Yates, 2004a) that are executed for extracting keywords; the most frequently used ones are tokenization, stopword removal, and stemming.

Tokenization involves dividing the stream of text into words. While in some languages such as English this is very straighforward and involves simply splitting the text using spaces and punctuation, in other languages, such as Chinese, finding words can be very difficult.

Stopwords are words that carry little semantic information, usually functional words that appear in a large fraction of the documents and therefore have little discriminating power for asserting relevance. In information retrieval, stopwords are usually

Figure 1 A Web search engine periodically downloads and indexes a subset of Web pages. This index is used for searching and ranking in response to user queries.

Figure 2 A sample inverted index.

discarded, also for efficiency reasons, as storing stopwords in an index takes considerable space because of their high frequency.

Stemming extracts the morphological root of every word. In global search engines, the first problem with stemming is that it is language-dependent, and while an English rule-based stemming works well, in some cases, such as Spanish, a dictionary-based stemmer has to be used, while in other languages, such as German and Arabic, stemming is quite difficult.

Other, more complex operations such as synonym translation, detecting multiword expressions, phrase identification, named entity recognition, word sense disambiguation, etc. are used in some application domains. However, some of these operations can be computationally expensive and if they have large error rates, then they can be useless and can even harm retrieval precision.

Inverted Index

An inverted index is composed of two parts: a vocabulary and a list of occurrences. The vocabulary is a sorted list of all the key words, and for each term in the vocabulary, a list of all the 'places' in which the key word appears in the collection is kept. Figure 2 shows a small inverted index, considering all words including stopwords. When querying, the lists are extracted from the inverted index and then merged. Queries are very fast because usually hashing in memory is used for the vocabulary, and the lists of occurrences are presorted by some global relevance criteria.

The granularity of the choice of the items in the list of occurrences determines the size of the index, and a small size can be obtained by storing only the document identifiers of the corresponding documents. If the search engine also stores the position where the term appears on each page the index is larger, but can be used for solving more complex queries such as queries for exact phrases, or proximity queries.

While the vocabulary grows sublinearly with the collection size, the list of occurrences can be very large. The complete inverted index can occupy from 10% to 20% of the space occupied by the actual collection. An inverted index does not fit in the main memory for a Web collection, so several partial indices are built. Each partial index represents only a

Figure 3 Indexing for Web search. (1) Pages are parsed and links and extracted. (2) Partial indices are written on disk when the main memory is exhausted. (3) Indices are merged into a complete text index. (4) Off-line link analysis can be used to calculate static link-based scores.

subset of the collection and these partial indices are later merged into the full inverted index.

In Figure 3 the main stages of the indexation process are depicted. During parsing, links are extracted to build a Web graph, and they can be analyzed later to generate link-based scores that can be stored along with the rest of the metadata.

Distributing Query Load

Query response time in today's search engines must be very fast, and should be done in parallel, involving several machines. For parallelization, the inverted index is usually distributed among several physical computers. To partition the inverted index, two techniques are used: the global inverted file and the local inverted file (Tomasic and Garcia-Molina, 1993).

When using a global inverted file, the vocabulary is divided into several parts containing roughly the same number of occurrences. Each computer is assigned a part of the vocabulary and all of its occurrences. Whenever a query is received, the query is sent to the computers holding the query terms, and the results are merged afterwards. Hence, load balancing is not easy.

When using a local inverted file, the document identifiers are divided, but each computer gets the full vocabulary. That is, step 3 in Figure 3 is omitted. A query is then broadcast to all computers, obtaining good load balance. This is the architecture used in the main search engines today, as building and maintaining a global index is difficult.

Query processing involves a central 'broker' that is assigned the task of distributing incoming queries and merging the results. As the results are usually shown in groups of 10 or 20 documents per page, the broker does not need to request or merge full lists, only the topmost results from each partial list.

Search engines exploit the fact that users seldom go past the first or second page of results. Search engines provide approximate result counts because they never perform a full merge of the partial result lists, so the total number of documents in the intersection can only be estimated. For this reason, when a user asks for the second or third page of results for a query, it is common that the full query is executed again.

Ranking

Text-Based Ranking

The vector-space model (Salton, 1971) is the standard technique for ranking documents according to a query. In this model, both a document and a query are seen as a pair of vectors in a space with as many dimensions as terms as there are in the vocabulary. In a space defined in this way, the similarity of a query to a document is given by a formula that transforms each vector using certain weights and then calculates the cosine of the angle between the two weighted vectors:

$$sim_{(q,d)} = \frac{\sum_t w_{t,q} \times w_{t,d}}{\sqrt{\sum_t w_{t,q}^2} \times \sqrt{\sum_t w_{t,d}^2}}$$

In a text-based information retrieval system, documents are shown to the user in decreasing order using this similarity measure.

A weighting scheme uses statistical properties from the text and the query to give certain words more importance when doing the similarity calculation. The most widely used scheme is the TF-IDF weighting scheme (Salton and Buckley, 1988), which uses the frequency of the terms in both queries and documents to compute the similarity.

TF stands for 'term frequency', and the idea is that if a term appears several times in a document it describes the contents of that document better. The TF is usually normalized with respect to document length, that is, the parameter used is the frequency of term t divided by the frequency of the most frequent term in document d:

$$tf_{t,d} = \frac{freq_{t,d}}{\max_\ell freq_{\ell,d}}$$

IDF stands for inverse document frequency and reflects how frequent a term is in the whole collection. The rationale is that a term that appears in a few documents gives more information than a term that appears in many documents. If N is the number of documents and n_t is the number of documents containing the query term t, then $idf_t = \log \frac{N}{n_t}$.

Using these measures, the weight of each term in given by:

$$w_{t,q} = \left(\frac{1}{2} + \frac{1}{2} tf_{t,q}\right) idf_t, \; w_{t,d} = tf_{t,d}$$

The 0.5 added is to avoid a query term having 0 weight. Several alternative weighting schemes have been proposed, but this weighting scheme is one of the most widely used and gives good results in practice.

Connectivity-Based Ranking

Web pages sharing a link are more likely to be topically related than unconnected Web pages (Davison, 2000). The key hypothesis of connectivity-based ranking goes one step further, and asserts that a hyperlink from a page p' to a page p, means, in a certain way, that the content of page p is endorsed by the author of page p'.

For the same reasons that self-citations in academic literature should not confer authority, link analysis techniques must be aware of the fact that thousands of links can be created automatically by the same user:

> 'Unlike academic papers which are scrupulously reviewed, Web pages proliferate free of quality control or publishing costs. With a simple program, huge numbers of pages can be created easily, artificially inflating citation counts. Because the Web environment contains profit-seeking ventures, attention-getting strategies evolve in response to search engine algorithms. For this reason, any evaluation strategy which counts replicable features of Web pages is prone to manipulation' (Page *et al.*, 1998).

The algorithms for connectivity-based ranking based on this assumption can be partitioned into (Henzinger, 2001):

- Query-independent ranking, which assigns a fixed score to each page in the collection.
- Query-dependent ranking, or topic-sensitive ranking, which assigns a score to each page in the collection in the context of a specific query.

Query-Independent Ranking The Pagerank algorithm (Page *et al.*, 1998) is currently an important part of the ranking function used by the Google search engine. The definition of Pagerank is recursive, stating in simple terms that a page with high Pagerank is a page referenced by many pages with high Pagerank.

To calculate the Pagerank, each page on the Web is modeled as a state in a system, and each hyperlink as a transition between two states. The Pagerank value of a page is the probability of being in a given page when this system reaches its stationary state.

A good metaphor for understanding this is to imagine a 'random surfer', a person who visits pages at random, and upon arrival at each page, chooses an outgoing link uniformly at random from the links in that page. The Pagerank of a page is the fraction of time the random surfer spends at each page.

This simple system can be modeled by the following equation of a 'simplified Pagerank'. In this and the following equations, p is a Web page, $\Gamma^-(p)$ is the set of pages pointing to p, and $\Gamma^+(p)$ is the set of pages p points to.

$$Pagerank'(p) = \sum_{x \in \Gamma^-(p)} \frac{Pagerank'(x)}{|\Gamma^+(x)|}$$

However, actual Web graphs include many pages with no out-links, which act as 'rank sinks' as they accumulate rank but never distribute it to other pages. In the stationary state, only they would have Pagerank > 0. These pages can be removed from the system and their rank computed later. Also, we would like pages not to accumulate ranking by using indirect self-references (self-links are easy to remove), thus not passing all of their score to other pages. For these reasons, most of the implementations of Pagerank add 'random jumps' to each page. These random jumps are hyperlinks from every page to all pages in

the collection, including itself, which provide a minimal rank to all the pages as well as a damping effect for self-reference schemes.

In terms of the random surfer model, we can state that when choosing the next step, the random surfer either chooses a page at random from the collection with probability ε, or chooses to follow a link from the current page with probability $1-\varepsilon$. This is the model used for calculating Pagerank in practice, and it is described by the following equation:

$$Pagerank(p) = \frac{\varepsilon}{N} + (1-\varepsilon) \sum_{x \in \Gamma^{-}(p)} \frac{Pagerank(x)}{|\Gamma^{+}(x)|}$$

where N is the number of pages in the collection, and the parameter ε is typically between 0.1 and 0.2, based on empirical evidence. Pagerank is a global, static measure of the quality of a Web page, very efficient in terms of computation time, as it only has to be calculated once at indexing time and is later used repeatedly at query time.

Note that Pagerank can also be manipulated and in fact there are thousands or millions of Web pages created specifically for the objective of deceiving the ranking function:

> 'Among the top 20 URLs in our 100 million page Pagerank calculation using teleportation to random pages, 11 were pornographic, and they appear to have all been achieved using the same form of link manipulation. The specific technique that was used was to create many URLs that all link to a single page, thereby accumulating the Pagerank that every page receives from random teleportation, and concentrating it into a single page of interest' (Eiron *et al.*, 2004).

Another paradigm for ranking pages based on a Markov chain is the absorbing model (Amati *et al.*, 2003). In this model, the original Web graph is transformed by adding, for each node, a 'clone node' with no out-links. Each clone node p' is only linked from one node in the original graph p. When this system reaches the stationary state, only the clone nodes have probabilities greater than zero. The probability of the clone node p' is interpreted as the score of the original node p.

A different paradigm for static ranking on the Web is the network flow model (Tomlin, 2003) for ranking pages. A (sub)graph of the Web is considered as carrying a finite amount of fluid, and edges between nodes are pipes for this fluid. The ranking of a page is related to the maximum amount of flow through a node in this network.

Query-independent ranking summarizes each page on the Web with a single number, or a pair of numbers, but as the creators of Pagerank note, "the importance of a Web page is an inherently subjective matter that depends on readers interests, knowledge and attitudes" (Page *et al.*, 1998); this is why query-dependent ranking is introduced to create ranking functions that are sensitive to user's needs.

Figure 4 Expansion of the root set with $k=5$ and $d=2$. k is the number of pages in the root set, and d is the maximum number of back-links to include in the neighborhood set.

Query-Dependent Ranking In query-dependent ranking, the starting point is a 'neighborhood graph': a set of pages that is expected to be relevant to the given query. This graph is built by starting with a set of k pages containing the query terms; this set can be built using the list of results given by a full-text search engine. This *root set* is augmented by its 'neighborhood', which comprises all (or a large sample) of the pages directly pointing to, or directly pointed to by, pages in the root set.

Figure 4 depicts the process of creation of the neighborhood set. The idea of limiting the number of pages added to the neighborhood set by following back links to at most a parameter d was not part of the original unbounded d proposal, but was introduced later (Bharat and Henzinger, 1998).

It is customary that when considering links in the neighborhood set, only links in different Web sites are included, as links between pages in the same Web site are usually created by the same authors as the pages themselves, and do not reflect the relative importance of a page for the general community.

The most linked pages in the neighborhood set are usually not the best candidates (Yuwono and Lee, 1996). Ordering pages by number of in-links performed poorly when compared with pure content-based analysis.

The HITS algorithm (Kleinberg, 1999) is based on considering that relevant pages can be either 'authority pages' or 'hub pages'. An authority page is expected to have relevant content for a subject, and

Figure 5 Hubs and authorities in a small graph. Node 4 is the best hub page, as it points to many authorities, and nodes *b* and *g* are the best authority pages.

a hub page is expected to have many links to authority pages. These two characteristics have a mutually reinforcing relationship: a page with high authority is pointed to by many pages with a high 'hubness' and vice-versa, as shown in Figure 5.

HITS produces two scores for each page, called authority score and hub score, using an iterative method of computation. The algorithm suffers from several drawbacks in its pure form (Bharat and Henzinger, 1998):

1. Not all the documents in the neighborhood set are about the original topic ('topic drifting').
2. There are nepotistic, mutually reinforcing relationships between hosts.
3. There are many automatically generated links.

Problem (1) is the most important, as while expanding the root set, it is common to include popular pages that are highly linked, but unrelated to the query topic. The solution is to use analysis of the contents of the documents and/or anchor texts and pruning the neighborhood graph by removing the documents that are too different from the query.

Problems (2) and (3) can be avoided using the following heuristic: if there are k edges from documents on a host to documents in another host, then each edge is given a weight of $1/k$. This gives each document the same amount of influence on the final score, regardless of the number of links in that specific document.

A different approach to query-dependent ranking is topic-sensitive Pagerank (Haveliwala, 2002). In this ranking scheme, scores for each page are precomputed at indexing time, using an algorithm similar to Pagerank. Each score represents the importance of a page for each topic from a set of predefined topics. At query time, the ranking uses the query to assign weights to the different topic-sensitive Pagerank scores of each page.

Crawling the Web

The large volume of the Web implies that any Web crawler can only download a fraction of the existent-Web pages within a given time, so it needs to prioritize its downloads. The high rate of change of the Web implies that by the time the crawler is downloading the last pages from a site, it is very likely that new pages have been added to the site, or that pages that have already been updated or even deleted.

Crawling the Web, in a certain way, resembles watching the sky in a clear night: what we see reflects the state of the stars at different times, as the light travels different distances. What a Web crawler gets is not a 'snapshot' of the Web, because it does not represent the Web at any given instant of time (Baeza-Yates and Ribeiro-Neto, 1999). The last pages being crawled are probably very accurately represented, but the first pages that were downloaded have a high probability of having been changed. This idea is depicted in Figure 6.

A crawler requires a smart scheduling policy for downloading Web pages, and this may become a harder problem in the future, as the amount of information on the Web can potentially grow faster than the available bandwidth for Web crawlers.

> 'Given that the bandwidth for conducting crawls is neither infinite nor free it is becoming essential to crawl the Web in a not only scalable, but efficient way if some reasonable measure of quality or freshness is to be maintained' (Edwards *et al.*, 2001).

The behavior of a Web crawler is the outcome of a scheduling policy that is mostly concerned with which pages to download and in which order (selection policy) and how to re-visit pages (re-visit policy) without overloading Web sites (politeness policy).

Selection Policy

There are several types of Web crawlers. A Web search engine concerned with only one country or one region is called a 'vertical search engine' and uses a crawler specifically designed for this purpose. In the case of a vertical crawler or an intranet crawler, the problem is easy, as the selection policy of pages is mostly related to selecting by a domain name.

On the other end, on a global Web search engine, the selection policy deals mostly with when to stop

Figure 6 The search engine's view of the Web represents the state of Web pages at different times, as the view of the sky at night presents the state of stars at different times.

crawling, as the space of Web pages is infinite. In this regard, a usual criteria is link depth, i.e., starting from the home page and following links up to a certain level (Baeza-Yates and Castillo, 2004).

There is a third kind of selection policy that is used by topical crawlers (for instance: the crawler of a search engine specialized in real estate). In this case, the importance of a page for a crawler can be expressed as a function of the similarity of a page to a given query. This is called 'focused crawling' (Chakrabarti *et al.*, 1999). The main problem in focused crawling is that in the context of a Web crawler, we would like to be able to predict the similarity of the text of a given page to the query **before** actually downloading the page. The performance of focused crawling depends mostly on the richness of links in the specific topic being searched, and focused crawling usually relies on a general Web search engine to provide starting points.

Re-visit Policy

The Web has a very dynamic nature, and crawling a fraction of the Web can take a long time, usually measured in weeks or months. By the time a Web crawler has finished its crawl, many events could have happened.

From the search engine's point of view, there is a cost associated with not detecting an event, and thus having an outdated copy of a resource. The most widely used cost functions are freshness and age (Cho and Garcia-Molina, 2000).

1. Freshness. This is a binary measure that indicates whether the local copy is accurate or not. The freshness of a page p in the repository at time t is defined as:

$$F_p(t) = \begin{cases} 1 & \text{if } p \text{ is equal to the local copy at time } t \\ 0 & \text{otherwise} \end{cases}$$

2. Age. This is a measure that indicates how outdated the local copy is. The age of a page p in the repository, at time t is defined as:

$$A_p(t) = \begin{cases} 0 & \text{if } p \text{ is not modified at time } t \\ t - \text{modification time of } p & \text{otherwise} \end{cases}$$

The objective of the crawler is to keep the average freshness of pages in its collection as high as possible, or to keep the average age of pages as low as possible. These objectives are not equivalent: in the first case, the crawler is only concerned with **how many** pages are out-dated, while in the second case, the crawler is concerned with **how old** the local copies of pages are.

Cho and Garcia-Molina (2003a) proved the surprising result that, in terms of average freshness, it is better to re-visit pages with a uniform frequency than to re-visit pages with a frequency proportional to their rate of change. The explanation for this result comes from the fact that, when a page changes too often, the crawler will waste time by trying to re-crawl it too fast and still will not be able to keep its copy of the page fresh.

Politeness Policy

The use of Web crawlers is useful for a number of tasks, but comes with a price for the general community. Web crawlers use a lot of network resources and

Figure 7 Typical high-level architecture of a Web crawler.

can potentially overload servers with more requests than they can handle.

A partial solution to these problems is the robot exclusion protocol (Koster, 1996), which is a standard for administrators to indicate which parts of their Web servers should not be accessed by robots. As for the interval between accesses to the same Web site, they vary between 20 seconds and 3–4 minutes. It is worth noting that even when being very polite, and taking all the safeguards to avoid overloading Web servers, some complaints from Web server administrators are received. Brin and Page note that: "... running a crawler which connects to more than half a million servers ... generates a fair amount of email and phone calls" (Brin and Page, 1998).

Web Crawler Architecture

A crawler must have a good crawling strategy, as noted in the previous sections, but it also needs a highly optimized architecture. Building a high-performance crawling system presents a number of challenges related to network efficiency and robustness (Shkapenyuk and Suel, 2002).

Web crawlers are a central part of search engines, and details of their algorithms and architecture are kept as business secrets. When crawler designs are published, there is often an important lack of detail that prevents others from reproducing the work. There are also emerging concerns about 'search engine spamming' that prevent major search engines from publishing their ranking algorithms. The typical high-level architecture of Web crawlers is shown in Figure 7.

Some important general-purpose crawlers include the WebCrawler (Pinkerton, 1994), which was used to build the first publicly available full-text index of the Web, the Internet Archive Crawler (Burner, 1997), which is used to archive periodic snapshots of a large portion of the Web and the Google Crawler (Brin and Page, 1998), which is described in some detail, but the reference is only about an early version. In addition to these specific crawler architectures, there are general crawler architectures described in (Chakrabarti, 2003; Baeza-Yates and Castillo, 2002).

Web Characterization

Web Size

During the last 3 years, about 10 million Web sites have appeared yearly, and in March 2005 over 60 million Web sites were found by Netcraft's Web server survey. As for the number of Web pages, the leading search engine today, Google indexed over 8 billion (10^9) pages in November 2004. This figure can only be taken as a lower bound. Even large search engines cover only a portion of the publicly available content (Lawrence and Giles, 2000); it is shown that no search engine indexed more than 16% of the Web in 1999.

Currently, most of the content on the Web cannot be found by following links, but is only accessible through query forms. This is called the 'Hidden Web' (Raghavan and Garcia-Molina, 2001), and it is believed to hold one or two orders of magnitude more information than the public pages. And, although the amount of information on the Web is certainly finite, Web applications can generate arbitrarily many pages and it can be argued that the number of pages on the Web is potentially infinite (Baeza-Yates and Castillo, 2004).

Figure 8 Examples of a random network and a scale-free network, with the major hubs highlighted in the scale-free network. Each graph has the same number of nodes and links. Note that both graphs were chosen to be connected and display well, so they are not entirely random.

Web Dynamics

When studying document updates, the data is obtained by repeated access to a subset of pages. In all cases, the results are only an estimation of the actual values because they are obtained by polling for events (changes), not by the resource notifying events, so it is possible that between two crawler accesses a Web page changes more than once.

If changes to a given page occur at independent intervals – if page change is a memoryless process – then it can be modeled as a Poisson process (Brewington *et al.*, 2000). The probability that a search engine's copy of a page is up to date at a certain time decreases exponentially if the page is not revisited. Under this model of page changes, the rate of change of a given page can be estimated based on previous observations (Cho and Garcia-Molina, 2003b), especially if the Web server provides the last modification date of the page every time it is visited.

However, it is worth noting that most Web page changes exhibit certain periodicity – because most of the updates occur during business hours in the relevant time zone for the studied sample – so the estimators that do not account for this periodicity are more valid on the scales of weeks or months than on smaller scales.

The methodologies and goals for studies on Web page changes vary widely. Some researchers focus on the lifespan of pages – the time it takes for a page to disappear from the Web – as they are concerned with the availability of Web content. For instance, in the case of scholarly publications, in 4 years about 50% of the links are no longer valid (Spinellis, 2003).

Other studies focus on Web page changes: in a large-scale study of 150 million pages over 10 weeks (Fetterly *et al.*, 2003), 65% of the pages did not change at all, while 30% of the pages had only minor changes and 5% changed substantially. It is also known than the .com domain is more dynamic than .edu and .gov (Cho, 2000) and that highly linked pages change more frequently (Douglis *et al.*, 1997).

Link Structure

The link structure on the Web emerges as the result of collective actions, and as such, it has properties that diverge from a pure random network. "While entirely of human design, the emerging network appears to have more in common with a cell or an ecological system than with a Swiss watch" (Barabási, 2001).

Scale-free networks, as opposed to random networks, are characterized by an uneven distribution of links. These networks are characterized as networks in which the distribution of the number of links $\Gamma(p)$ to a page p follows a power law:

$$Pr(\Gamma(p) = k) \propto k^{-\theta}$$

A scale-free network can be interpreted as a graph in which a few highly-linked nodes act as 'hubs', keeping most of the nodes in the network together, as depicted in Figure 8.

On the Internet, the geographical and physical connectivity of nodes forms a scale-free network, as well as the network of links between Web pages and the network of e-mail exchanges. Outside the realm of computer science, scale-free networks appear in several contexts, for instance, the network of acquaintances, friends, and social popularity in human interactions, the graph of citations in scientific publications, and the networks of protein interaction in cellular metabolism.

There are certain models of the growth of scale-free networks. The preferential attachment model (Barabási and Albert, 1999), is a 'rich-get-richer' model in which each new Web page creates links to existent Web pages with a probability distribution that is not uniform, but proportional to the current in-degree of existent Web pages. This generates a power-law, but the resulting graph differs from the actual Web graph in other properties such as the presence of small, tightly connected communities.

Another generative model is the 'copy' model (Kumar *et al.*, 2000), in which new nodes choose an

existent node at random and copy a fraction of the links of the existent node. This also generates a power law. These two models can be combined into a generative model that mixes preferential attachment with a baseline probability of gaining a link (Pennock *et al.*, 2002).

One of the characteristics of the Web that is more difficult to reproduce using generative models is its macroscopic structure. The most complete study of this subject (Broder *et al.*, 2000) focuses on the connectivity of a subset of 200 million Web pages from the Altavista search engine.

The study starts by identifying in the Web graph a single, large, strongly connected component, with all of the pages in this component able reach one another along directed links. They call the larger strongly connected component 'MAIN'. Starting in MAIN, if we follow links forward we find OUT, and if we follow links backward we find IN. All of the Web pages that are part of the graph but do not fit MAIN, IN, or OUT are part of other components as shown in Figure 9.

Components MAIN, IN, and OUT contain more than half the size of the Web, and as components in IN cannot be reached starting from MAIN, it is clear that for Web crawling, a good set of starting URLs is required. There is also a significant fraction of pages that can only be reached if the exact domain name is known; this is the ISLANDS part of the Web, and many Web sites start by being isolated and later join one of the other components (Baeza-Yates and Poblete, 2004).

Research Issues

There are many research issues in Web search. They can be divided roughly into two classes: data problems and user problems (Baeza-Yates, 2004b).

Among the data problems are volume, rapid change, the adversarial nature of the Web (spamming of metadata, content, and links), diversity of languages (e.g., cross-lingual retrieval), diversity of content (ranging from information and e-commerce sites to blogs and other new forms of Web publishing), Web server cooperation schemes for search engines, and multimedia retrieval, to name only a few.

On the user side, better query languages, user interfaces, and result visualizations are needed to cope with the information overload on the client side. The main open problem is to assess the quality of the results. They are usually relevant, but we will never know if we have all the relevant results, or if we have the best ones.

Weber, Albrecht Friedrich (1825–1901)

P C Sutcliffe, Colgate University, Hamilton, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Albrecht Friedrich Weber, born February 17, 1825 in Breslau, was an extraordinarily prolific Indologist who made major contributions to Vedic, Prakrit, and Jaina studies. The son of an economist, Weber studied Oriental (including Sanskrit, Persian, and Arabic) and classical philology as well as history at three universities, in Breslau, Bonn, and Berlin, from 1842–1845. After taking his degree in Breslau in 1845, he traveled to Paris and London with a grant from the Prussian Academy to view and collate manuscripts of the White Yajurveda. The results were published in three volumes from 1852–1859, comprising his first contribution to Vedic studies. In 1848, he became a professor in Berlin, where Bopp was his colleague, and remained there until his death on November 30, 1901.

A tireless worker, Weber published dozens of important monographs and articles in his lifetime as well as countless reviews of new works. Many of these were published in *Indische Studien*, a journal that he founded in 1850. Several important articles are collected in his *Indische Skizzen* of 1857 and *Indische Streifen* of 1868, 1869, and 1879. His book reviews from 1880–1896 are collected in *Litterarisch-kritische Streifen*, Vol. 18 of *Indische Studien* (1897).

One of Weber's most indispensable contributions to Sanskrit studies was his catalogue of the manuscripts of the Royal Library of Berlin (Robert Chambers's collection), which had been acquired in 1843, entitled *Handschriften-Verzeichnisse der Königlichen Bibliothek zu Berlin* (1853). Preparing the catalogue, Weber became very familiar with Vedic literature, resulting in his *Akademische Vorlesungen über indische Literaturgeschichte* ('Academic Lectures on Indian literary history') of the same year. Other important Sanskrit contributions reflect Weber's particular interest in finding connections and influences among ancient peoples and their literatures. In 'Das Mahabhasya des Patanjali' (*Indische Studien*, Vol. XIII, 1873), Weber used cultural and literary references in the Mahabhasya to create the first unified picture of the culture and historical context from which it came and posited Greek influence on the development of Indian drama. In *Über die Krishnajanmashtami* ('Krishna's Geburtsfest') ('Krishna's Birthday Festival') (*Indische Studien*, 1868), Weber argued for Christian influence on the Krishna legend. His most important Vedic work was his transcription of *Taittiriya-Samhita* (*Indische Studien* Vol. XI and XII, 1871, 1872).

In Prakrit studies, Weber edited the Saptasatakam of Hala in 1870 and Bhavanapala's commentary to it in 1883. He was also one of the first to learn about the Jains and their holy literature, and to spread this knowledge to the West, for example, in his *Über die heiligen Schriften der Jaina* (1883, *Indische Studien* Vol. XVI and XVII, 1183, 1885).

Weber's central position as a professor in Berlin with access to the manuscripts and editor of *Indisiche Studien* meant that he had great and lasting influence in Indology, and particularly on his students, the most famous of whom was William Dwight Whitney.

Weber, Max (1864–1920)

M Palma, Rome, Italy

© 2006 Elsevier Ltd. All rights reserved.

Max Weber was born in Erfurt on April 21, 1864, son of Max Weber, member of the Reichstag, and Helene Fallenstein, and died on June 14, 1920 of an illness later diagnosed as pneumonia. After enrolling at the University of Heidelberg, he later moved to Strassburg, Berlin and Göttingen. He received his Ph.D. in 1889, with a dissertation on the *History of the Commercial Societies in the Middle Ages* and 2 years later he obtained the Habilitation with a dissertation entitled *Roman agrarian history*. His early work was deeply appreciated by Theodor Mommsen: Weber soon became a reference figure of the academic world. In 1893 he married Marianne Schnitger, who after his death was responsible for the publication of all his major works. In 1896, after his call to Heidelberg to succeed Karl Knies, he began suffering from serious nervousness which led him to suspend his teaching duties until 1918. He spent the following years traveling, most of all across Italy. He began to recover from his psychological illness only in 1903, when he definitively resigned from his academic chair.

1904 was a prolific year for Weber: he joined Sombart and Jaffé in the editorship of the *Archiv für Sozialwissenschaft und Sozialpolitik*, which became the major organ for social sciences in Germany. Here he published most of his methodological essays, contributing to the foundation of sociology as a rigorous science. As an introduction to the new journal, he wrote the essay on 'Objectivity of social and social-political knowledge,' where he developed the concept of 'ideal type' as an arbitrary representation able to express a constellation of sense, a criterion constructed by the social scientist in order to present a coherent description of an object. Although most of his work remained unfinished, and his writing style has often been viewed as difficult and incomprehensible, Weber always struggled for a strict method in science theory. This new intellectual endeavor involved a great deal of scientific debates with his colleagues, from Rudolph Stammler to Eduard Meyer.

In 1904 he also had the opportunity to visit the United States, where he held a conference in St. Louis on the social structure of Germany. This 3-month journey deeply impressed him: it is easy to find its traces in his later work, starting from his contemporary and most famous work, *The Protestant ethic and the spirit of capitalism*, where he claimed that the spiritual origin of capitalism had to be found in the ascetic morality of the Calvinists.

In 1909 he started working at his unfinished masterpiece, *Economy and society* (1922), a massive attempt, in his historical view, to unify sociology and economics, comprehending a huge range of subjects, from law to social actions, from religious communities to the different kinds of power (legal, traditional, charismatic). Its last goal can be defined as the explanation of the conditions which made it possible for Western world to develop such a rational (capitalistic) organization of both social and economical life.

Before the outbreak of World War I, he engaged himself in the foundation of the German Society of Sociology. His house in Heidelberg was frequently visited by eminent scholars: within the Weber circle, one could find Ernst Troeltsch and Werner Sombart, sociologists such as Simmel and Michels, neokantian philosophers such as Lask, Rickert, and Windelband, young scholars such as Jaspers, Lukács, and Bloch. To define his position in controversies, in 1913 he wrote the essay 'Some categories of interpretative sociology,' which intended to be the conceptual premises to *Economy and society*, determining the new discipline as a nomothetical one and establishing general rules of social behavior. During wartime, after a momentary lapse of nationalism – as a volunteer, he took charge of some bureaucratic tasks in the hospital of Heidelberg – he realized that German military policy would not lead anywhere. He started a consistent campaign against submarine warfare, due to involve the United States in the conflict, advising political reforms and supporting the Reichstag's role and a restriction of the powers of the Kaiser. Such a political attitude led him to be considered as a prophet of doom. At the end of the war, he was a founding member of the Deutsche Demokratische Partei, playing an important preliminary role in the writing of the Weimar Constitution and taking part as an expert in the Versailles Conference. He failed to be elected as a member in the democratic Parliament of the new Republic.

Even during this hectic political engagement, he managed to work on his *Sociology of religion*, the result of long work on the social impact of behaviors commanded or oriented by religious doctrines. His essays concerned the economical ethic of Hinduism, Buddhism, Judaism, Taoism and Confucianism.

Earlier in 1918, he started lecturing in Vienna and afterwards in Munich, in 1919, where he held two famous lectures on science and politics as a vocation. In the first conference he expressed his view that

scientific work must remain independent of personal values. In the second one, he distinguished between the ethic of responsibility, taking responsibility for the consequences of actions, and the ethic of intentions, rather preferring the purity of the moral law.

A critical edition of his work – *Max Weber Gesamtausgabe* – is now being edited by Mohr (Siebeck), Germany.

Webster, Noah (1758–1843)

C Neis, University of Potsdam, Potsdam, Germany

© 2006 Elsevier Ltd. All rights reserved.

Noah Webster was born in West Hartford, Connecticut, on October 16, 1758 and died in New Haven on May 28, 1843. He was an American lexicographer, textbook author, and spelling reformer.

Born the son of a New England farmer, Webster inherited the Protestant pioneer heritage without being exposed to the most rigorous Puritanism. From 1774 to 1778, Webster attended Yale, where he was imbued with the Enlightenment's ideals and with revolutionary thought. After graduation, Webster returned to his father's farm but was soon forced to seek his own living. From 1779 to 1780, Webster worked as a teacher in Hartford and West Hartford. Unsatisfied with schoolteaching, he decided to dedicate himself to the legal profession. In 1781, he was admitted to the bar in Connecticut, but his economic situation soon compelled him to return to education. He opened his own school in Sharon, Connecticut, where he was acquainted with the Huguenot Reverend John Peter Tetard, with whom he studied languages and history. After several personal disappointments, Webster left Sharon and moved to Goshen, New York, where he headed a school from 1782 to 1783. This period proved to be a turning point in Webster's life: he became a prominent propagandist for the Revolution and an intrepid defender of the ideal of an independent utopian America. The stay at Goshen turned out to be very prolific; during that time, Webster wrote Part I of *A grammatical institute of the English language*, his famous *Spelling book*. The *Speller* taught millions of Americans to spell and influenced thousands of young Americans more than any other secular book. Until that time, schoolbooks had been written by Englishmen, but Webster wanted to render them suitable for revolutionary America. Even though Webster worked as a teacher only reluctantly at the beginning of his career, his *Speller* was the first step on his long journey to becoming the 'schoolmaster of America.' Linked with the speller were a *Grammar* (1784) and a *Reader* (1785), but these parts of the *Grammatical institute* never reached the popularity of the *Speller*. At the end of the book, Webster appended a federal catechism, but by the beginning of the 19th century, a moral catechism was substituted for it. The moralistic approach of the *Speller* was particularly emphasized in editions after 1787, which included a series of fables. Apart from this moral tract that served as a vehicle for the transmission of the Protestant ethic, the *Speller* served as a means of creating a national language. For Webster, one of the basic purposes of his book was to support the establishment of America's cultural independence and national pride. Furthermore, Webster wanted to foster the unity of America.

The second part of the *Grammatical institute*, the *Grammar*, was deeply influenced by Robert Lowth's (1710–1787) *A short introduction to grammar*. Like Lowth, Webster advocated the disentangling of

scientific work must remain independent of personal values. In the second one, he distinguished between the ethic of responsibility, taking responsibility for the consequences of actions, and the ethic of intentions, rather preferring the purity of the moral law.

A critical edition of his work – *Max Weber Gesamtausgabe* – is now being edited by Mohr (Siebeck), Germany.

Noah Webster was born in West Hartford, Connecticut, on October 16, 1758 and died in New Haven on May 28, 1843. He was an American lexicographer, textbook author, and spelling reformer.

Born the son of a New England farmer, Webster inherited the Protestant pioneer heritage without being exposed to the most rigorous Puritanism. From 1774 to 1778, Webster attended Yale, where he was imbued with the Enlightenment's ideals and with revolutionary thought. After graduation, Webster returned to his father's farm but was soon forced to seek his own living. From 1779 to 1780, Webster worked as a teacher in Hartford and West Hartford. Unsatisfied with schoolteaching, he decided to dedicate himself to the legal profession. In 1781, he was admitted to the bar in Connecticut, but his economic situation soon compelled him to return to education. He opened his own school in Sharon, Connecticut, where he was acquainted with the Huguenot Reverend John Peter Tetard, with whom he studied languages and history. After several personal disappointments, Webster left Sharon and moved to Goshen, New York, where he headed a school from 1782 to 1783. This period proved to be a turning point in Webster's life: he became a prominent propagandist for the Revolution and an intrepid defender of the ideal of an independent utopian America. The stay at Goshen turned out to be very prolific; during that time, Webster wrote Part I of *A grammatical institute of the English language*, his famous *Spelling book*. The *Speller* taught millions of Americans to spell and influenced thousands of young Americans more than any other secular book. Until that time, schoolbooks had been written by Englishmen, but Webster wanted to render them suitable for revolutionary America. Even though Webster worked as a teacher only reluctantly at the beginning of his career, his *Speller* was the first step on his long journey to becoming the 'schoolmaster of America.' Linked with the speller were a *Grammar* (1784) and a *Reader* (1785), but these parts of the *Grammatical institute* never reached the popularity of the *Speller*. At the end of the book, Webster appended a federal catechism, but by the beginning of the 19th century, a moral catechism was substituted for it. The moralistic approach of the *Speller* was particularly emphasized in editions after 1787, which included a series of fables. Apart from this moral tract that served as a vehicle for the transmission of the Protestant ethic, the *Speller* served as a means of creating a national language. For Webster, one of the basic purposes of his book was to support the establishment of America's cultural independence and national pride. Furthermore, Webster wanted to foster the unity of America.

The second part of the *Grammatical institute*, the *Grammar*, was deeply influenced by Robert Lowth's (1710–1787) *A short introduction to grammar*. Like Lowth, Webster advocated the disentangling of

English grammar from Latin rules. Nevertheless, Webster's *Grammar* borrowed heavily from the Latin model in the domain of methodology. Webster was not only influenced by Lowth, but also by Horne Tooke's *The diversions of Purley* (1786) whose principles he adopted in his *A philosophical and practical grammar of the English language*. In this work, Webster held that Anglo-Saxon was to be used as a linguistic basis for modern English. Although Webster did not particularly focus on grammar, his persisting attacks against the Latin tradition of grammar might have helped to establish an English grammar independent of the omnipresent Latin model.

The third part of the *Grammatical institute* was a *Reader* that introduced rules for reading and speaking. In this part, Webster's nationalism is clearly expressed by the choice of patriotic pieces. Because Webster was eager to promote his schoolbooks and to claim copyrights, in May of 1785 he started traveling between several major cities in the United States. After short periods in which he worked as schoolteacher and journalist, he returned to Hartford, where he married Rebecca Greenleaf in 1789. In the same year, he published his lectures on language as *Dissertations on the English language*, in which he wrote on the general history of language, on the elements of language, on the formation and corruption of language, and on linguistic discussions. The following years were dedicated to family life (Webster fathered seven children) and to several changes of domicile. After having published *A brief history of epidemic and pestilential diseases* in 1799, Webster began working on his *Dictionary* in 1800. In 1806, Webster published *A compendious dictionary of the English language*, in which he based the etymologies of words on their Saxon origins, thus adopting Tooke's conception. He aimed at a more phonetic spelling and pleaded for a moderate reform of orthography.

In 1808, Webster converted to evangelical Protestantism. This conversion was of crucial importance for his most famous work: *An American dictionary of the English language,* which was finished in Cambridge, England, in 1825, but published in New York in 1828. In the dedication, Webster contended that language was of divine origin and that the primordial language was Chaldaic. His *American dictionary* is based on a religious conception that attempts to find the spiritual truth hidden by etymologies. Although the *Dictionary* reveals Webster's ignorance of the achievements of comparative grammar and a general lack of knowledge of European linguistic scholarship, Webster's *American dictionary* – with its 70 000 words – is one of the most astonishing achievements in the history of lexicography. Among the numerous dictionaries that followed this model, Merriam-Webster's dictionary may be considered as the most direct descendant of Noah Webster's tradition.

In keeping with his religious conversion, Webster published an edition of the Bible in 1833, a work he considered the most important of his life. Webster died in 1843, leaving to posterity a multitude of writings on a variety of topics (language, education, politics, religion, science, medicine, etc.), but he is especially remembered for his *Dictionary.* The name 'Webster' is still synonymous throughout the English-speaking world with correct spelling, authoritative definitions, and the concept of a dictionary.

Wegener, Philipp (1848–1916)

W Bublitz and V Eisenlauer, University of Augsburg, Augsburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Because of his original development of a communicative and functional approach to language, Wegener is regarded as a predecessor of German pragmatic thinking and British contextual linguistics. Born near Magdeburg, he studied Classical and German philology, comparative linguistics, and philosophy in Marburg and Berlin. After completing a doctoral thesis on Greek and Latin cases in 1871, he entered upon a career as a high school teacher. Although he remained a schoolteacher all his life, he never gave up scholarly research.

Under the influence of his university teachers (notably the philologist Moritz Haupt, the classicist Ernst Curtius, and the linguist and psychologist Heymann Steinthal), Wegener published in comparative linguistics, psycholinguistics and, because of his keen interest in the local dialects he grew up with, dialectology. In one of these studies, he put forward the idea of correlating different choices of words with the different settings in which they occur. This idea was the cornerstone of his subsequent research into 'situations' and their impact on the linguistic form of a speech event. His investigations culminated in his main work, *Untersuchungen über die Grundfragen des Sprachlebens*, in which he demonstrates that verbal expressions are best described not in isolation but as part of the totality of a person's *Lebensäußerungen* and as embedded in the 'context of situation.' Pursuing questions such as 'How does language function as a means of communication?', he argued that language is not merely an instrument for the representation of thoughts but a powerful means of acting purposefully to influence other people's minds and actions. The central concept of 'context of situation' consists, *inter alia*, of the 'situation of perception,' the 'situation of remembrance or consciousness,' and the 'situation of culture,' which have a great impact on the linguistic form of a speech event and ultimately on its comprehension. Wegener also introduces a functional bipartition to be found in any utterance: the 'exposition,' which serves to clarify the situation or to secure the preconditions of understanding, and the 'logical predicate,' i.e., the representation of the speaker's actual communicative aim. Understanding involves a cognitive process of continually limiting and specifying expectations pre-arranged by encyclopedic knowledge, speech situation, and the preceding verbal context. Wegener's last contribution to linguistics, *Der Wortsatz*, discusses the controversial subject of the sentence, its origin, nature, and definition.

Wegener's influence on general linguistics (Hermann Paul, Karl Brugmann) and on Karl Bühler, whose functional model of language is entirely compatible with Wegener's ideas, was considerable. His work was also a strong inspiration for Bronislaw Malinowski, Alan Gardiner, and John Rupert Firth, who used his concepts, especially that of the 'context of situation,' to establish a new school of functional and contextual linguistics in England. There are even some similarities between Michael Halliday's notion of language as a social semiotic system and Wegener's view that language is a part of social life.

Weinreich, Uriel (1926–1967)

A Sunshine, Columbia University, New York, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

In his remarkable career, cut short by a fatal illness, Uriel Weinreich made seminal contributions to various areas of the language sciences including bilingualism, semantics, sociolinguistics, lexicography, dialectology, language change, and Yiddish linguistics. Weinreich was born in Vilna, the elder of two sons. Max Weinreich, his father, was an outstanding figure in the study of Yiddish language and culture and one of the founders, in 1925, of the YIVO Institute in Vilna (relocated in 1940 to New York). In August 1939, when Weinreich was 13, his father took him to Copenhagen *en route* to a linguistic conference in Brussels. While they were abroad, Germany invaded Poland. Unable to return home, the Weinreichs settled in New York in early 1940.

Weinreich wrote his Columbia University doctoral dissertation (1951) under André Martinet's supervision and revised it for publication as *Languages in contact* (1953). While rooted in Weinreich's own experience as a member of a multilingual community who, moreover, had immigrated to a new linguistic environment, the study drew upon Weinreich's fieldwork in Switzerland in 1950 among bilingual Romansch speakers.

From 1951 through 1967, Weinreich taught linguistics at Columbia. With the help of the Atran Foundation and Martinet, Weinreich introduced Yiddish studies into Columbia's graduate curriculum. His students included William Labov and Marvin Herzog, with whom he wrote 'Empirical Foundations for a Theory of Language Change,' a conference paper presented and published after Weinreich's death. Directly, and through his students, he influenced many scholars beyond Columbia.

It was while conducting his dissertation research in Switzerland that the idea of creating an atlas of Yiddish-speaking Jewry occurred to Weinreich (B Weinreich, 1991: 9). This project, an important part of Weinreich's legacy, has established a comprehensive and systematic geolinguistic record of a culture destroyed in the Holocaust. Methodologically, the atlas was significant because Weinreich sought to execute it on the principles explored in his paper 'Is a Structural Dialectology Possible?' (1954). To process the atlas data, Weinreich pioneered the use of computers for dialectology (Sunshine, 1994: 60).

It is difficult to summarize Weinreich's contributions to linguistics because of the striking variety of his interests. He wrote *College Yiddish* (1949), a pedagogical grammar still widely used. He maintained an active interest in lexicology, not only writing critiques of dictionaries and theoretical explorations of lexicology, but also compiling the *Modern Yiddish-English/English-Yiddish dictionary* (1968). Posthumously published, this dictionary remains the standard reference in the English-speaking world. Weinreich began writing on semantics when this was still of peripheral concern to most linguists and soon recast his thinking in generative terms. 'Problems in the Analysis of Idioms' (Weinreich, 1969) is one of his many important papers and reflects his inclination to take on subjects generally regarded as refractory to linguistic analysis.

Weinreich served the greater academic community in his role as editor of periodicals and collective volumes in linguistics and Yiddish studies. He was also an early advocate of Chomsky's thinking (Koerner, 1989: 118).

Weinreich was married to Beatrice Silverman Weinreich, a scholar of Jewish folklore. They had two children and collaborated on several works, including a bibliography on *Yiddish language and folklore* (1959) and the design and methodology of the *Language and culture atlas of Ashkenazic Jewry* (Herzog *et al.*, (eds.) 1992, 1995, 2000). Weinreich died of melanoma in 1967. He had not yet turned 41. Labov deems Weinreich "one of the most profound and powerful linguists of our time."

Weinreich began writing on semantics when this was still of peripheral concern to most linguists and soon recast his thinking in generative terms. 'Problems in the Analysis of Idioms' (Weinreich, 1969) is one of his many important papers and reflects his inclination to take on subjects generally regarded as refractory to linguistic analysis.

Weinreich served the greater academic community in his role as editor of periodicals and collective volumes in linguistics and Yiddish studies. He was also an early advocate of Chomsky's thinking (Koerner, 1989: 118).

Weinreich was married to Beatrice Silverman Weinreich, a scholar of Jewish folklore. They had two children and collaborated on several works, including a bibliography on *Yiddish language and folklore* (1959) and the design and methodology of the *Language and culture atlas of Ashkenazic Jewry* (Herzog *et al.*, (eds.) 1992, 1995, 2000). Weinreich died of melanoma in 1967. He had not yet turned 41. Labov deems Weinreich "one of the most profound and powerful linguists of our time."

Welmers, William E. (1916–1988)

G T Childs, Portland State University, Portland, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

In the field of linguistics, William E. Welmers was the first great American Africanist. He was also one of the first Africanists to focus on synchronic description rather than diachrony. Most importantly, he generously shared his wide linguistic knowledge and applied it to practical matters of teaching and literacy. A brilliant field linguist, Welmers could knock down one language for breakfast and have another one figured out by dinner. Although most of his own work was done in West Africa, he was conversant with the Bantu languages and personally researched at least one Afroasiatic language.

Born and raised in the Midwest, Welmers's father was a professor of Greek at New Hope College where the son earned his undergraduate degree in philosophy (*summa cum laude*) in 1936. He then went on to Westminster Theological Seminary in Philadelphia and continued work in classical and biblical languages, as well as in theology and received several degrees there. Continuing his graduate studies in Near Eastern languages at the University of Pennsylvania, Welmers shifted to African languages due to war needs. His Ph.D. dissertation (1943) was supervised by Zellig Harris and described the grammar of Fanti, a major language of Ghana. As is well known, the main linguistic consultant was a young Ghanaian student named Kwame Nkrumah, later to become head of independent Ghana and much else.

Welmers's interest in language pedagogy began in the same period when he was involved, as part of the war effort, with the teaching of Japanese and Chinese. When the war ended, he set off to Africa (with his wife and son, a daughter was born there), where he worked among the Kpelle for the Lutheran Mission of Liberia. The three strands of his life's work were set: language pedagogy, service to his church, and language description. The rest of his career would see him making important contributions in all three areas. Welmers had a tremendous record of service to his church, to his students and university, and to both national and international organizations.

After the work in Liberia, Welmers set off across Africa from west to east, now with two young children, on a trip taking two years, as a fellow of the American Council of Learned Societies. He worked on languages belonging to several branches of Niger–Congo and on a Cushitic language of Eritrea. He returned to a position at Cornell, where he stayed for four years, and then returned to Liberia with the Lutheran Mission. On his return from Liberia he accepted a position at Hartford Theological Seminary (1955–1960) and finally at the University of California at Los Angeles, where he stayed until his retirement in 1982.

Welmers was very much an inspirational teacher and was vitally concerned with how languages were taught. His *magnum opus* and best-known work, *African language structures*, appeared in 1970 (published in 1973) was undertaken on the instigation of his students. It is an immense compendium of linguistic facts peppered with personal anecdotes and was the only book of its kind for many years. His success as a teacher can be seen in how many of his students went on to positions in major research universities. The Department of Linguistics at UCLA was for many years the best place to study for those interested in African languages, and much of the school's reputation was due to his inspirational teaching and scholarship.

Welsh

P W Thomas, School of Welsh, Cardiff University, Wales, UK

© 2006 Elsevier Ltd. All rights reserved.

Demographic Features

According to the 2001 census, 582 000 people, or 20.8% of the total population of Wales, claimed to be able to speak Welsh; almost 798 000, or 28.4% of the population, claimed to have at least one language skill in Welsh. Before 2001 successive censuses had recorded a decline in the number of Welsh speakers: 10 years previously, in 1991, there were 508 000 speakers who comprised 18.7% of the population. Apart from some very young children, all Welsh speakers in Wales are bilingual and can also speak English.

There are no official counts of Welsh speakers outside Wales but surveys commissioned by S4C, the Welsh television channel, suggest that there are more than 200 000 in England. One particular area where emigrants from Wales continue to speak Welsh is Patagonia, in the Chubut province of Argentina. The first settlers arrived in 1865, hoping to found a 'New Wales'; many of their descendants are bilingual in Welsh and Spanish.

The density and numbers of Welsh speakers show considerable geographic variation. For example, 69% of the population of Gwynedd, in the north-west, can speak the language, compared to 11% of the population of Cardiff, the capital, in the south-east. But while the 69% of Gwynedd represents almost 78 000 speakers, the 50% of Carmarthenshire in the south-west represents more than 84 000 individuals. There are also more Welsh speakers in urban than rural areas. For example, there are almost 26 000 speakers in rural Powys in mid Wales, but almost 28 000 in the post-industrial Rhondda-Cynon-Taf valleys, 29 000 in the southern city of Swansea, and 32 500 in Cardiff, the capital.

The increase in Welsh speaking is the result of growth on two main fronts. The first, and most obvious, is among school children. In addition to the growing number of Welsh-medium schools, it became compulsory in 1990 for children in English-medium state schools to learn Welsh up to the age of 14; in 1999 the upper age limit was raised to 16. These changes are reflected in the 2001 census, which recorded that 40.8% of all children between the ages of 5 and 15 could speak Welsh. The second growth area in the number of Welsh speakers is the many thousands of adults who are learning the language.

The change in the ability to use Welsh is accompanied by increasing institutional support. A Welsh television channel, S4C, was established in 1982, followed in 1998 by S4C Digital, which broadcasts over 80 hours of Welsh television a week. There are several local radio stations and a national Welsh

Voiced fricatives		v	ð	z	(ʒ)				
Nasals	m		n				ŋ		
Liquids			l	r					
Semivowels	w					j			

language radio station, Radio Cymru, which broadcasts about 126 hours a week. Several hundred Welsh language books and periodicals are published a year and a network of some 50 local Welsh papers which are produced several times a year by volunteers.

The use of the Welsh language is promoted by the Welsh Language Board, a government-funded body that was established by the 1993 Welsh Language Act, which states that Welsh and English should be treated equally in the administration of justice and in public business. Public bodies in Wales must submit schemes to the Board that describe the provision they make for the language. The aims of the Board seem to have general support: according to a recent opinion poll 67% of the people in Wales thought that more should be done to promote the language.

Periods of Welsh

The periods of the development of Welsh are conventionally divided into Early Welsh (up to the end of the 8th century and represented by a few names), Old Welsh (from the 9th to the 11th centuries, represented by glosses and fragments of prose and verse), Middle Welsh (from the 12th to the 14th centuries and represented by a substantial body of prose and verse), and Modern Welsh.

Linguistic Features

Alphabet

Written Welsh uses the Roman alphabet. Particular orthographic conventions include several digraphs, e.g. ⟨th⟩ for /θ/, ⟨dd⟩ for /ð/, ⟨ch⟩ for /χ/ and ⟨ll⟩ for /ɬ/; ⟨w⟩ and ⟨i⟩ represent the consonants /w/ and /j/ or the vowels /u/ and /i/ respectively, and ⟨y⟩ represents /ə/ and /ɨ(ː)/.

Phonemic Inventory

The vowels, diphthongs, and consonants of Welsh are listed in Table 1. The main dialect variations with respect to this inventory are the absence of /ɨ(ː)/ (and diphthongs closing to /ɨ/) in southern Welsh, of /ə/ in the extreme south-west, and of /h/ and voiceless /r̥/ in the south-east. Conservative northern speakers will substitute /s/ for /z/, which features in some loans from English. Two affricates – /tʃ/ and /dʒ/ – feature in loanwords and in dialects. Other salient dialect differences are listed in Table 2.

Consonant Mutation

In common with the other Celtic languages, some of the initial consonants of Welsh words vary according to their grammatical context, for example:

/kaːθ/ ⟨cath⟩
'cat'
/və ŋhaːθ/ ⟨fy nghath⟩
'my cat'
/i gaːθ/ ⟨ei gath⟩
'his cat'
/i χaːθ/ ⟨ei chath⟩
'her cat'

Such consonantal changes are traditionally called mutations. They may be triggered by a preceding

Table 2 Three dialect differences

Feature	*Example*	*Northern*	*Southern*
Realisation of /χ/ preceding /w/	(ch)with 'left'	χwiːθ	(h)wiːθ
Vowel length preceding /ɬ/	call 'sane'	kaɬ	kaːɬ
Vowel length preceding /sp, st, sk, ɬt/	gw(a)llt	gwaːɬt	gwaɬt

word, such as the personal pronouns in the above examples, or by grammatical context. For example, the object of a verb will mutate but not the subject:

Gwelodd ddyn.
saw-PAST man
'he/she saw a man'

Gwelodd dyn.
saw-PAST man
'a man saw'

There are three mutations, which may affect up to nine consonants (Table 3).

Table 3 The consonant mutations

Radical	*Soft*	*Nasal*	*Spirant*
/p/	/b/	/mh/	/f/
/t/	/d/	/nh/	/θ/
/k/	/g/	/ŋh/	/χ/
/b/	/v/	/m/	
/d/	/ð/	/n/	
/g/	–	/ŋ/	
/m/	/v/		
/ɬ/	/l/		
/r̥/	/r/		

Vocabulary

The core vocabulary of Welsh is Celtic, for example, *drws* 'door', *dyn* 'man', and *haul* 'sun'. There are some 800 loanwords from Latin, mostly borrowed during the Roman occupation (43–410 A.D.); many of these refer to architectural and religious innovations, for example, *eglwys* 'church' from Latin *ecclēsia*, *ffenestr* 'window' from *fenestra*, and *pont* 'bridge' from *pontem*. There are also many thousands of loans from English. A very few of these may be dated to the Old English period, but the numbers increase from the medieval period onward; examples are *cwpan* 'cup', *sêt* 'seat', *trowsus* 'trousers'.

There are some dialect differences in the vocabulary, particularly between northern and southern varieties; for example, 'grandmother' is *nain* in northern Welsh but *mam-gu* in southern Welsh; 'out' is *allan* in the north but *mâs* in the south; and 'with' is *efo* in the north but *gyda* in the south. Standard Welsh may use both *nain* and *mam-gu,* but only *allan* and *gyda*. Speakers are generally tolerant of such variation.

Keeping pace with developments in English vocabulary has occupied lexicographers since the 18th century. More recently, educationalists who are concerned with delivering the school curriculum through the medium of Welsh have planned the elaboration of Welsh vocabulary through coinage, borrowing, and adaptation. The standardization of subject-specific vocabularies is undertaken professionally.

Syntax

Welsh is a VSO language. For example:

Prynodd y ferch gar.
bought the girl car.
'the girl bought a car.'

Welsh has a definite article but no indefinite article. Adjectives tend to follow the noun they qualify, for example:

car coch
car red
'red car'

Welsh has grammatical gender. Some adjectives have feminine and plural forms, a feature that is more prominent in formal styles and northern dialects, for example:

ceffyl gwyn
horse white
'white horse'

caseg wen
mare white-FEMININE
'white mare'

ceffylau gwynion
horses white-PLURAL
'white horses'

Numerals have masculine/neutral and feminine forms for 1 (*un*), 2 (*dau, dwy*), 3 (*tri, tair*) and 4 (*pedwar, pedair*). The gender of the numeral *un* is apparent only when nouns beginning with certain consonants follow it; cf.

ci, un ci
dog-MASCULINE, one dog
cath, un gath
cat-FEMININE, one cat

Stylistic Variation

Informal spoken varieties of Welsh show considerable variation, and may be heavily influenced by English vocabulary, morphology, syntax, and intonation,

with frequent code-switching. Formal varieties tend to be more conservative and to favor native features.

Welsh Lexicography

A Hawke, University of Wales Dictionary of the Welsh Language, Aberystwyth, UK

© 2006 Elsevier Ltd. All rights reserved.

For a small language community, Welsh lexicography has had a surprisingly long and rich history, beginning with the early 'bardic glossaries' that survive in some 15th-century transcripts, but the first printed dictionary was William Salesbury's Welsh–English dictionary of 1547, *A dictionary in Englyshe and Welshe*, intended as an aid to learning English. Between 1604 and 1607, Thomas Wiliems translated the English of Thomas Thomas's Latin–English dictionary into Welsh, and this work, although unpublished, formed the basis of the Latin–Welsh part of John Davies's extremely influential *Antiquae linguae Britannicae . . . dictionarium duplex* (1632).

Many later Welsh dictionaries were based on Davies's work, such as Thomas Jones's *Y Gymraeg yn ei disgleirdeb* (1688) and Thomas Richards's 1753 dictionary, which was largely a Welsh–English version of the 1632 work. The first published English–Welsh dictionary, by John Roderick (Siôn Rhydderch), appeared in 1725, followed by John Walter's comprehensive English–Welsh dictionary of 1770–1794. William Owen[-Pughe]'s misguided but hugely influential *Welsh and English dictionary* (1793–1803) attempted to trace the etymology of all words back to 'primitive particles' and created many new words in the process, some of which have entered the standard language.

Most 19th-century dictionaries were derivative, but a few were innovative, such as the English–Welsh dictionary of Edward Williams (also known as Caerfallwch) (1850), who coined many new (mostly technical) words. This and a number of other dictionaries were reprinted in the United States, a practice continued today by Hippocrene Books. The year 1848 saw the beginning of a long line of Welsh–English and separate English–Welsh dictionaries published by William Spurrell, and revised repeatedly by J. Bodvan Anwyl between 1914 and 1937. The publishing house Collins engaged Henry Lewis and (later) others to revise this, and the work, in several condensed editions, has sold in excess of a quarter million copies. Silvan Evans prepared two substantial works: a two-volume English–Welsh dictionary

with frequent code-switching. Formal varieties tend to be more conservative and to favor native features.

Welsh Lexicography

A Hawke, University of Wales Dictionary of the Welsh Language, Aberystwyth, UK

© 2006 Elsevier Ltd. All rights reserved.

For a small language community, Welsh lexicography has had a surprisingly long and rich history, beginning with the early 'bardic glossaries' that survive in some 15th-century transcripts, but the first printed dictionary was William Salesbury's Welsh–English dictionary of 1547, *A dictionary in Englyshe and Welshe*, intended as an aid to learning English. Between 1604 and 1607, Thomas Wiliems translated the English of Thomas Thomas's Latin–English dictionary into Welsh, and this work, although unpublished, formed the basis of the Latin–Welsh part of John Davies's extremely influential *Antiquae linguae Britannicae . . . dictionarium duplex* (1632).

Many later Welsh dictionaries were based on Davies's work, such as Thomas Jones's *Y Gymraeg yn ei disgleirdeb* (1688) and Thomas Richards's 1753 dictionary, which was largely a Welsh–English version of the 1632 work. The first published English–Welsh dictionary, by John Roderick (Siôn Rhydderch), appeared in 1725, followed by John Walter's comprehensive English–Welsh dictionary of 1770–1794. William Owen[-Pughe]'s misguided but hugely influential *Welsh and English dictionary* (1793–1803) attempted to trace the etymology of all words back to 'primitive particles' and created many new words in the process, some of which have entered the standard language.

Most 19th-century dictionaries were derivative, but a few were innovative, such as the English–Welsh dictionary of Edward Williams (also known as Caerfallwch) (1850), who coined many new (mostly technical) words. This and a number of other dictionaries were reprinted in the United States, a practice continued today by Hippocrene Books. The year 1848 saw the beginning of a long line of Welsh–English and separate English–Welsh dictionaries published by William Spurrell, and revised repeatedly by J. Bodvan Anwyl between 1914 and 1937. The publishing house Collins engaged Henry Lewis and (later) others to revise this, and the work, in several condensed editions, has sold in excess of a quarter million copies. Silvan Evans prepared two substantial works: a two-volume English–Welsh dictionary

(1852, 1858) and an ambitious unfinished historical dictionary, *A dictionary of the Welsh language* (*A–ennyd*, 1887–1906).

In the 20th century, dictionaries such as H. Meurig Evans's much reprinted *Geiriadur Mawr* and *Geiriadur Newydd* have generally been rather disappointing, being little more than wordlists. Notable exceptions include Geraint Lewis's *Geiriadur Gomer i'r Ifanc* and Meirion Davies's *Dictionnaire Français–Gallois, Gallois–Français* (2000). The comprehensive *Welsh Academy English–Welsh Dictionary* (1995) has been a boon to translators, although it has been criticized for being poorly organized and overinclusive. A number of recent dictionaries have been aimed specifically at Welsh learners, the best being Gareth King's *Oxford pocket modern Welsh dictionary* (2000), although it describes the colloquial rather than the literary language. Two historical dictionaries include John Lloyd-Jones's magisterial (but sadly unfinished) *Geirfa Barddoniaeth Gynnar Gymraeg* (1931–1963, *A–heilic*), essentially a dictionary of medieval literary Welsh, and *Geiriadur Prifysgol Cymru: a dictionary of the Welsh language* (4 vols., 1950–2002), the standard historical dictionary. Work is now in progress on a much-needed second edition.

A recent trend is the growing number of online dictionaries, both institutional and amateur, of a generally high standard.

Wenker, Georg (1852–1911)

W H Veith, University of Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Georg Wenker, the son of a bookbinder and art dealer, was born in Düsseldorf, Rhineland. He was a volunteer in the Franco-Prussian war of 1870–1871. Between 1872 and 1875, he studied Classical and Germanic Philology, Comparative Linguistics, Philosophy, and History in Zurich, Bonn, and finally in Marburg. In 1876, he received a doctor's degree from the University of Tübingen. Thereafter, he was a trainee at the regional library of Düsseldorf and then at the university library in Marburg, where he became a curator in 1883. He became a chief librarian there in 1897. In the same year, the title of a 'Professor of German philology' was conferred on him, without obligation to teach.

Wenker's scientific career began with his doctoral thesis, for which he needed information on German dialects. His search was of no avail. In a subsequent project, he collected dialect data in his Rhenish homeland and published the results in a small book, *The Rhenish patois* (1877). This was the starting point for the enlargement of the territory of investigation by making dialect atlases of the Rhineland (1878) and of northern and central Germany (1881). From 1884 on, he expanded his research to the territory of the 'Deutsches Reich,' but this atlas was never published. Based on Wenker's data collection, map-making continued under his successor Ferdinand Wrede, so that there finally were 1646 unpublished maps of the dialects of the 'Deutsches Reich.'

Georg Wenker was the founder of dialect cartography and of the 'indirect method' in dialectology. Inspired by the need that arose from his doctoral thesis, his initial idea was to find dialect borders; then it became a curiosity about what language diversity was like. This drove him on to do basic research and put the results on dialect maps – at first, in the Rhineland, then in northern Germany, and then in the entire 'Deutsches Reich.' From the very beginning (1877), his maps were empirically based on 42 (later on 40) Standard German sentences, the so-called 40 'Wenker sentences' (altogether 475 words), which were composed under prestructural aspects with regard to the historical grammar and, consequently, to the structural approach to dialects in the *Kleiner Deutscher Sprachatlas* (see Veith *et al*., 1984–1999). Their translation into local dialects was done by public school children as native speakers; their teachers assisted them and wrote the translations down ('indirect method'). The reliability of these written records depended on the teachers' abilities for sound discrimination and their abilities to depict the sounds they heard using the insufficient alphabet of Standard German. This method of exploring was different from the direct method used, e.g., for the French linguistic atlas (ALF) and its data collection (1897–1901), which was based on a face-to-face phonetic transcription.

An extract of the Wenker maps was published between 1926 and 1956 as *Deutscher Sprachatlas* (DSA) (128 maps, but in comparison with the Wenker maps, the atlas was extended to the territories of Austria, Switzerland, etc., altogether about 50 000 locations). In the DSA, almost all German dialects in Central Europe were represented. Because the Wenker maps were not published in full, two more projects had to follow: the computerized Concise linguistic atlas of German (*KDSA. Kleiner deutscher Sprachatlas*, 1984–1999) and the *Digital Wenker Atlas* (DiWA) published on the Internet since 2001 and comprising all Wenker maps in color.

The Language and Its Dialects

Greenlandic, or Kalaallisut, is an Eskimo language (*see* **Eskimo-Aleut**). Greenland, or Kalaallit Nunaat, is geographically and culturally part of the North American continent; however, since 1721, it has been a territory of Denmark. In 1979 Greenland obtained autonomy over local governance, and Greenlandic was named the national language along with Danish. Today there are more than 50 000 speakers of Greenlandic, the vast majority of whom live in Greenland, although a sizable population is to be found in Denmark. There are three major dialects of Greenlandic: Polar Eskimo, spoken in the Thule region, East Greenlandic, spoken on the east coast, and West Greenlandic, spoken along most of the western coast. West Greenlandic is the dialect most widely spoken in Greenland, as well as being the standard dialect for purposes of political administration, education, church, and media. The dialect region stretches from Upernavik in the north to Kap Farvel in the south. Four subdialects are generally recognized: the subdialect spoken in Upernavik; North West Greenlandic (Uummannaq, and the Disko Bay region), Central West Greenlandic (Sisimiut to south of Nuuk); and South West Greenlandic (from north of Paamiut to south of Nanortalik), according to Dorais, 1996. The subdialects differ slightly in various aspects of their phonology and lexicon; thus, the Upernavik dialect, sharing a feature of East Greenlandic, tends to replace /u/ with /i/ under certain conditions, and Northwest Greenlandic retains a historical retroflex /ʃ/, whereas the Central and Southwestern dialects have merged /ʃ/ with /s/. The Greenlandic spoken in the capital city, Nuuk, tends to contain more Danish loans and syntactic features than the language spoken in other settlements, due to a relatively significant Danish population, as well as to its concentration of administrative and political activities. The Central West Greenlandic subdialect has long been the accepted spoken and written standard, and it will serve as the basis of the description given below.

Historiography of Descriptive Work

Greenland has seen several waves of immigration from both Eskimo and European populations. The most recent Eskimo groups are estimated to have arrived in Northern Greenland by the end of the 12th century and in Southern Greenland by the end of the 15th century. There is some evidence they made contact with the first European immigrants, the Norse, who had arrived in the late 10th century. There is, however, scant linguistic evidence of Norse influence on Greenlandic, and the Norse had disappeared by the 16th century. From the late Middle Ages, European whalers, traders, and explorers made their way up the coast of Greenland; the first written records of West Greenlandic are wordlists they compiled during the 16th and 17th centuries, although some of the words collected appear to represent a trade pidgin (van der Voort, 1996).

The first systematic grammatical descriptions of the language date from the beginning of the Danish colonial era in the 18th century and were made by Lutheran and Moravian missionaries. The first of these was a collaborative work from 1725 between the missionary Hans Egede and his assistant Topp, with the help of Egede's son, Poul. This served as the basis of a dictionary, published in 1750, and the first complete grammar, in 1760, by P. Egede. Later descriptions were modeled on P. Egede's work, the most notable being O. Fabricius' grammar (1791, rev. 1801) and dictionary (1804). In 1851 Samuel Kleinschmidt published his grammar of Greenlandic;

Volksschullehrer gesammeltem Material aus ca. 30,000 Orten. ('Linguistic atlas of north and central Germany. On the basis of systematically, with the aid of the school teachers collected material from about 30 000 locations.') Strasbourg & London: Trübner.

The Greenlandic spoken in the capital city, Nuuk, tends to contain more Danish loans and syntactic features than the language spoken in other settlements, due to a relatively significant Danish population, as well as to its concentration of administrative and political activities. The Central West Greenlandic subdialect has long been the accepted spoken and written standard, and it will serve as the basis of the description given below.

Historiography of Descriptive Work

Greenland has seen several waves of immigration from both Eskimo and European populations. The most recent Eskimo groups are estimated to have arrived in Northern Greenland by the end of the 12th century and in Southern Greenland by the end of the 15th century. There is some evidence they made contact with the first European immigrants, the Norse, who had arrived in the late 10th century. There is, however, scant linguistic evidence of Norse influence on Greenlandic, and the Norse had disappeared by the 16th century. From the late Middle Ages, European whalers, traders, and explorers made their way up the coast of Greenland; the first written records of West Greenlandic are wordlists they compiled during the 16th and 17th centuries, although some of the words collected appear to represent a trade pidgin (van der Voort, 1996).

The first systematic grammatical descriptions of the language date from the beginning of the Danish colonial era in the 18th century and were made by Lutheran and Moravian missionaries. The first of these was a collaborative work from 1725 between the missionary Hans Egede and his assistant Topp, with the help of Egede's son, Poul. This served as the basis of a dictionary, published in 1750, and the first complete grammar, in 1760, by P. Egede. Later descriptions were modeled on P. Egede's work, the most notable being O. Fabricius' grammar (1791, rev. 1801) and dictionary (1804). In 1851 Samuel Kleinschmidt published his grammar of Greenlandic;

this is the earliest thorough linguistic description of an American native language and it is widely seen as the first modern, synchronic linguistic description of a language. Kleinschmidt also created a standard, linguistically accurate orthography for Greenlandic, which was maintained until 1972, when a more modern orthography was introduced to reflect important morphophonological changes in Greenlandic. Descriptive work on West Greenlandic has continued to the present, and important scholars include Thalbitzer, one of the first to document through sound recordings, Schultz-Lorentzen, Bergsland, and Fortescue. In addition to general descriptions, more recent work has included specialized studies of phonology (e.g., Rischel, 1972), syntax (e.g., Sadock, 1991), and discourse (e.g., Berge, 1997).

Phonetics and Phonology

West Greenlandic phonology is characterized by having few consonants and vowels and restrictions on vowel and consonant clusters, as well as on final consonants. Thus, only vowels and stops are found word finally; the only allowable diphthongs are /iV/, /Vi/, or /uV/; and consonant clusters are only found medially and consist mostly of geminates, with the exception of /rC/ combinations (see Table 1).

Some features of Greenlandic are common to other Eskimo languages, including traces of a fourth vowel (*see* **Eskimo-Aleut**), and a rich morphophonology. Particular to West Greenlandic is the extreme degree of consonant cluster assimilation, which has taken place in the historic period.

Old Greenlandic	paurqi-ngnig-tar-fik
New	paaqqi-nnit-tar-fik
	take.care.of-ANTI-HABIT-place
	'nursing home'

Restrictions on vowel or consonant clusters and a productive morphology, with complex rules for adding morphemes, have led to more opaque word formations than in other Eskimo languages. (For more on the morphophonology, see Rischel, 1974 and Fortescue, 1984.)

Morphology/Syntax

Greenlandic is an extremely polysynthetic language, with a large number of derivational affixes and complex inflection. Words consist of a root (or base), typically from zero to five suffixes known as postbases (although more than five are possible and quite normal), and an inflectional ending; with one nonproductive exception, there are no prefixes. Roots generally are subcategorized for part of speech; nominal roots will require nominal inflection, and verbal roots will require verbal inflection. The most important parts of speech are the open classes of nouns and verbs; adjectives and adverbs tend to be verbally derived. There are also a rich system of demonstratives, a limited set of particles, a limited set of fossilized adverbs and adjectives, and few but common clitics. There are several hundred derivational postbases, many of which are highly productive. These are commonly classified into four categories: those which derive nouns from nominal bases (NN); those that derive verbs from nominal bases (NV); those that derive verbs from verbal bases (VV); and those that derive nouns from verbal bases (VN). Some also attach to other parts of speech, e.g., particles;-nnit-and-tar-in the example above are both VV, and-fik is VN. NN and NV are shown in the following example:

Table 1 Phoneme inventory for West Greenlandic

Manner/Place	*Labial*	*Dental*	*Palatal*	*Velar*	*Uvular*
Stops	p	t		k	q
Fricatives −v	f	s	(ʃ = [s])	x	
+v	v			g	R
Nasals	m	n		ŋ	
Liquids			ɬ = [ll]		
			l		
Glides	j			(w)	
Vowels: a, aa, i, ii, u, uu					

Standard orthography is in brackets; parentheses indicate subdialect forms or questionable phonemic status.

inuk-rsuaq-u-voq
man-big-COP-3sing.INDIC
N-NN-NV-INFL
'he is a giant'

As this example shows, verbalizing postbases can create verbal structures that 'incorporate' a verbal argument; that is, a subject or object can be brought into the verbal structure. There is some theoretical debate as to whether or not Eskimo languages can be called incorporating (e.g., Baker, 1988), but within the field of Eskimo linguistics, there is a long tradition of using the term 'incorporation' for structures of the type exemplified above. Even inflected forms can incorporate:

aappalut-toq	illu-mi-iC-voq
red-PART	*house-LOC-COP-3sing.INDIC*
'he is in the red house'	

Nominal inflection includes eight cases as well as possessive and person markers, which are also inflected for case. There are two grammatical cases, absolutive and ergative (or relative), and six oblique cases, including instrumental (a default case with many

Figure 1 Major Greenlandic dialects and West Greenlandic subdialects.

functions, both grammatical and nongrammatical), locative, ablative, allative, vialis, and equalis.

Verbal inflection is semifused and includes marking for dependence, mood, transitivity, person, and number. Verb moods are typically categorized as either independent or dependent. Sentences often consist of strings of subordinate clauses with dependent mood marking and a superordinate clause headed by a verb with independent mood marking. Independent moods include the indicative, interrogative, optative, and imperative moods. Dependent moods include the conditional, causative (indicating causation or action prior to that expressed by the independent clause), contemporative (indicating action contemporaneous with that expressed by the independent clause), and participial (used in object clauses, as an alternative to the indicative in narration, and in other discourse contexts). For an example of clause chaining from West Greenlandic (*see* **Eskimo-Aleut**).

Ergativity and transitivity have long been topics of interest in the study of Greenlandic. Transitive clauses are headed by verbs with subject and object person marking, and the arguments are marked with ergative and absolutive case. Intransitive and antipassive clauses are headed by verbs with pronominal marking of the subject and nouns take absolutive case. Objects of antipassive clauses take instrumental case. Traditionally, these are seen as related to definiteness of the object, although they may reflect topicality (Berge, 1997).

'the man sees/saw a bear' (indefinite, or topic introduction)

At least one relatively major syntactic theory has been developed to account for Greenlandic morphosyntax. This is Autolexical Theory, developed by Sadock (1991, 2003) and based in part on GPSG. It allows morphology and syntax to require structures that may not always result in exact matching, as in the stranded modification of a locative phrase in the sentence 'he is in the red house' given above.

Lexicon

Modern Greenlandic has seen an influx of new lexical items as a result of colonial experience and modernization. The earliest evidence of this is seen in early Bible translations, with the heavy use of Danish loans relating to Christianity. Some of these loans have been well integrated into the language, for example, *palasi*, from Danish *præst* 'priest', while others have been replaced by Greenlandic coinages. Greenlandic has actively incorporated new words in its lexicon, through relexicalization of obsolete terms (e.g., *issat* 'snow goggles' are now 'eyeglasses'), borrowing (*kaffi* 'coffee'), and coinage (Petersen, 1976, Berge and Kaplan, 2005). There is some evidence for the increased use of passive formations and nominalizations in the lexicon, perhaps as a result of the influence of journalistic style and literacy.

Semantics/Discourse/Sociolinguistics

Little work has been done to date on other aspects of linguistic description, especially including semantics, discourse, and sociolinguistics, although the body of work in these areas is steadily increasing. There have been reports on child language acquisition (Fortescue, 1985), bilingualism (Jacobsen, 1997), and discourse (Berge, 1997), among others. More sociolinguistic and semantic studies have been done of neighboring dialects, such as Inuktitut.

State of the Language Today

Unlike many other native languages of North America, West Greenlandic is not endangered and is, in fact, undergoing normal language development and change, although there was a period of endangerment. During the mid–20th century, increasing encroachment of the Danish language led to almost two generations of speakers who appeared to be losing their fluency in Greenlandic. In response, Greenlandic became one of the national symbols of the political campaigns for autonomy from Danish rule in the 1970s. With the establishment of Home Rule in 1979, Greenlandic was given the status of national language along with Danish. Language loss was successfully reversed, although there may have been some lasting effects of bilingualism on the dialect spoken in Nuuk. Factors that have contributed to this reversal include a history of education and literacy in Greenlandic, a wealth of materials in the language, and political support. From earliest colonial times, education was established in West Greenlandic, and literacy was common. Today Greenlandic can be chosen as a medium of instruction throughout the years of formal schooling, and there have been efforts to include it as the language of instruction at Ilisimatusarfik, the University of Greenland. The first books in Greenlandic were published in the 1850s and the first newspaper, *Atuagagdliutit,* shortly thereafter. Since then, there have been several thousand books and articles published in Greenlandic, *Atuagagdliutit* has been in continuous print since its inception, and there are today two bilingual newspapers (in Danish and Greenlandic), local television and radio stations with Greenlandic programming, and more.

West Papuan Languages

G Reesink, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Introduction

In the area between Timor and the adjacent islands Alor and Pantar (126 °E) and the Cenderawasih Bay of the Indonesian province Papua (136 °E), roughly 50 of the more than 800 Papuan languages are spoken (see **Figure 1**).

These West Papuan languages do not form one family, in spite of earlier attempts to establish a "large West Papuan Phylum" (Cowan, 1957, 1960). More recently, the West Papuan Phylum has been restricted to the languages of North Halmahera (NH) and the Bird's Head Peninsula (Voorhoeve, 1975; Wurm, 1981, 1982), whereas the South Bird's Head (SBH) languages and some languages on the western tip of the Bomberai peninsula are claimed to form one family with those of Timor-Alor-Pantar (TAP), forming a subgroup within the largest Papuan family proposed thus far, the Trans New Guinea (TNG) family (McElhanon and Voorhoeve, 1970; Voorhoeve, 1975; Stokhof, 1975; Wurm, 1982; Pawley, 1998; Foley, 2000; Ross, 2004).

The West Papuan languages of North Halmahera and the Bird's Head could form a distantly related family, on the basis of (i) pronominal forms for1sg as **t/d-* and **n-* for 2sg; (ii) the number-ablaut (sg is *a*, pl is *i*), found in TNG, is also attested in a number of West Papuan languages, and (iii) a small number of possible cognates. Some of these show some overlap with the TNG evidence, for example, reflexes of **niman* 'louse' (Pawley, 1998; Reesink, 2004). Although a few families have been established with reasonable certainty, the evidence for linguistic relatedness between them is so meagre that no firm conclusions should be drawn at present. Rather, the West Papuan languages form an areal network of basically unrelated families (North Halmahera, West BH, and two East BH families (Meyah-Sougb; and Hatam-Mansim) and a number of isolates in the center of the Bird's Head (Maybrat, Abun, Mpur) and Yawa in the Cenderawasih Bay. They share a number of typological features, not only between them but also with the Austronesian languages spoken in this same region, betraying approximately four millenia of contact since the Austronesians first arrived in the Moluccas and around the Bird's Head (Bellwood, 1985).

Typological features

Verbal Complex

As typical of Papuan languages, the constituent order of the clause is SOV in TAP, NH, SBH, and Yawa, all of which also have a verbal prefix for (animate)

West Papuan Languages

G Reesink, Leiden University, Leiden, The Netherlands

Introduction

In the area between Timor and the adjacent islands Alor and Pantar (126 °E) and the Cenderawasih Bay of the Indonesian province Papua (136 °E), roughly 50 of the more than 800 Papuan languages are spoken (see Figure 1).

These West Papuan languages do not form one family, in spite of earlier attempts to establish a "large West Papuan Phylum" (Cowan, 1957, 1960). More recently, the West Papuan Phylum has been restricted to the languages of North Halmahera (NH) and the Bird's Head Peninsula (Voorhoeve, 1975; Wurm, 1981, 1982), whereas the South Bird's Head (SBH) languages and some languages on the western tip of the Bomberai peninsula are claimed to form one family with those of Timor-Alor-Pantar (TAP), forming a subgroup within the largest Papuan family proposed thus far, the Trans New Guinea (TNG) family (McElhanon and Voorhoeve, 1970; Voorhoeve, 1975; Stokhof, 1975; Wurm, 1982; Pawley, 1998; Foley, 2000; Ross, 2004).

The West Papuan languages of North Halmahera and the Bird's Head could form a distantly related family, on the basis of (i) pronominal forms for1sg as **t/d-* and **n-* for 2sg; (ii) the number-ablaut (sg is *a*, pl is *i*), found in TNG, is also attested in a number of West Papuan languages, and (iii) a small number of possible cognates. Some of these show some overlap with the TNG evidence, for example, reflexes of **niman* 'louse' (Pawley, 1998; Reesink, 2004). Although a few families have been established with reasonable certainty, the evidence for linguistic relatedness between them is so meagre that no firm conclusions should be drawn at present. Rather, the West Papuan languages form an areal network of basically unrelated families (North Halmahera, West BH, and two East BH families (Meyah-Sougb; and Hatam-Mansim) and a number of isolates in the center of the Bird's Head (Maybrat, Abun, Mpur) and Yawa in the Cenderawasih Bay. They share a number of typological features, not only between them but also with the Austronesian languages spoken in this same region, betraying approximately four millenia of contact since the Austronesians first arrived in the Moluccas and around the Bird's Head (Bellwood, 1985).

Typological features

Verbal Complex

As typical of Papuan languages, the constituent order of the clause is SOV in TAP, NH, SBH, and Yawa, all of which also have a verbal prefix for (animate)

Figure 1 Map of West Papua.

object, which is the normal crossreference for the recipient with a verb like 'give.' Less typical is the configuration that has an additional verbal prefix for subject, as found in NH and SBH languages.

The region of the west Papuan languages is one of three in which Papuan languages are found that do not have a V-final order, the other two being the Torricelli languages and some of the East Papuan languages. Some of the NH and most BH languages have a rather strict SVO order, often with a subject prefix as the only verbal affixation.

Tense-Aspect-Mood morphology is generally poor or completely absent, as in Abun. Some aspect or mood prefixation is found in languages of the EBH. Inanwatan has tense marked by suffixation, whereas the TAP languages mark aspect that way. In the 'non-tensed' languages, predicative adjectives behave as verbs (see Stassen, 2003), whereas 'tensed' Inanwatan verbalizes adjectives by means of a copula (De Vries, to appear).

All West Papuan languages, whether OV or VO, have a clause-final negative adverb, in some cases with no morphosyntactic means to delineate its scope (Reesink, 2002). They also agree in having clause-final aspectual adverbs, such as 'already.'

Nominal Complex

The order of constituents in the Noun Phrase is in all West Papuan languages: Noun–Adjective–Numeral–Demonstrative, whereas a few NH languages have a prenominal article in addition. All of them make a distinction between alienable and inalienable possession. The latter construction consists of a possessor prefix on the possessed noun (body-part and kinship terms), which is generally identical to either the subject or object prefix, if the latter is available in the language.

Numeral classifiers are widely available in the West Papuan languages, Meyah having the most complex system, whereas its relative Sougb and their (very distantly?) related neighbour Hatam only have a vestige (see Reesink, 2002).

Pronominal systems A gender distinction (masculine; feminine; and, in some languages, neuter) for 3sg forms seems to be an old Papuan feature that links the West Papuan languages with most of the non-TNG languages along the north coast of New Guinea, as far as the Solomon Islands. The TAP languages, and on the Bird's Head, the isolate Abun and the two EBH families lack this feature.

The inclusive-exclusive opposition for nonsingular first person seems to be an Austronesian feature that has found its way into all the WP languages, except three central BH isolates, Maybrat, Abun, and Mpur.

Tone

Tonal contrasts are found in Mpur, with four phonemic tones (Odé, 2002) and Abun with three (Berry and Berry, 1999), whereas Meyah (Gravelle, 2002) and Sougb (Reesink, 2002) are pitch-accent languages with two contrastive tones. Ma'ya and Matbat are AN languages of the Raja Ampat Islands that have a Papuan substrate of four contrastive tones (Remijsen, 2001).

Papuan and Austronesian Contact

The SVO order with concomitant prepositions can be seen as a diffusion into many WP languages, in addition to the inclusive–exclusive opposition. There seems to have been more diffusion in the other direction: almost all Austronesian languages in the WP sphere have a clause-final negator, a preposed possessor, and the alienable–inalienable distinction for possessive construction, albeit that the latter is expressed by possessor suffixes on the possessed noun, rather than by prefixes as in the Papuan languages. The typological contrast between western AN languages and those of this area, given by Himmelmann (to appear), focuses precisely on these 'Papuanisms' (see Klamer, Reesink, and Van Staden, to appear). It thus suggests a scenario of original Papuan-speaking communities that shifted to 'imperfectly' learned Austronesian languages. Prolonged contact between these communities allowed for further convergence to a linguistic area of AN and Papuan languages in the Moluccas and the western peninsula of New Guinea.

Westermann, Diedrich Hermann (1875–1956)

S Pugach, The Ohio State University, Lima, OH, USA

© 2006 Elsevier Ltd. All rights reserved.

Together with Carl Meinhof, Diedrich Westermann is usually considered one of the main founders of the discipline of African linguistics – *Afrikanistik* – in Germany (*see* **Meinhof, Carl Friedrich Michael (1857–1944)**). He was born on June 24, 1875, in Baden, a town in lower Saxony near the city of Bremen, and died there on May 31, 1956. When he was in elementary school, Westermann studied several subjects and was tutored privately at home (Pasch, 2005). Upon finishing school in 1891 he became a postman, but in 1895 joined the North German Missionary Society. He received training to become a missionary in Basel and Tübingen, and, after a brief stay in England, traveled to Togo as a teacher for the mission. Once there, Westermann quickly became proficient in Ewe and began his linguistic career, which would span five decades. At the request of the North German Missionary Society he completed a linguistic description of Ewe, and went on to publish a handbook, dictionary, and grammar of the language (Westermann, 1903, 1905–1906, 1907; Stoecker, 2004). Illness forced him to return to Germany from Togo a first time in 1903, and permanently in 1907. Throughout he was a prolific scholar, writing mainly on West African languages that were classified as Nigritic or Sudanic (Jungraithmayr and Möhlig, 1983).

In 1907 Westermann took up a post teaching African languages at the Seminar for Oriental Languages in Berlin, where for two years he worked alongside Meinhof, an expert in Bantu languages. When Meinhof left Berlin for the Hamburg *Kolonialinstitut* in 1909, Westermann's star quickly rose in Berlin, and in 1910 he was appointed professor there. While Westermann was no longer traveling to Africa as a missionary, he did go as a scholar, and in 1910 the government of the Sudan, which was then under British imperial control, asked him to visit and continue his linguistic studies. After the trip he published a comparative work on the languages of the Sudan and a book on the Shilluk people (Westermann, 1911, 1912). His research also compared the Nigritic languages to Bantu ones, as he followed Meinhof in attempting grammatical and morphological classifications of African languages.

Westermann was interned in Spain for much of World War I, and when it was over began to work closely with his British colleagues. In 1926 Westermann and Henri Labouret were named the first directors of the Institute for African Languages and Cultures in London, demonstrating that Westermann had become a linguist of international repute. While at the Institute, Westermann developed a new uniform orthographic system for transcribing and printing African languages, which was called Westermann-script. He hoped that this system would replace the one that Richard Lepsius had instituted in the 19th century and which Westermann found too confusing and cumbersome to be practical (*see* **Lepsius, Carl Richard (1810–1884)**). Meinhof argued for the Lepsius system, breaking with Westermann and ending their friendship. Convinced of the significance of phonetics and tonology, Westermann conducted intensive studies in both disciplines during his tenure at the Institute and published a practical guide to phonetics with Ida Ward (Westermann and Ward, 1933). Westermann's activities extended beyond the Institute, as he was an editor of its journal, *Africa*, from 1928–1940, founder of the *Institut für Lautforschung*, and a professor in Berlin at the Seminar for Oriental Languages throughout. Additionally, Westermann was not only a linguist, but also a noted scholar of religion and ethnology. Although he resigned from the North German Missionary Society in 1908, he remained an honorary member for his entire life, and wrote copiously on the Protestant mission and its role in Africa, as well as on native religions. As an ethnologist, Westermann distinguished himself with books on state-building in sub-Saharan Africa (Westermann, 1952) and individual studies of specific ethnic groups such as the Shilluk and Kpelle (Westermann, 1912, 1921).

Introduction

There are so many scholarly books that purport to tell or summarize the 'history' of linguistics that it may seem paradoxical to begin by suggesting that the whole question of whether linguistics has a history at all is itself controversial. (For a critical analysis of the notion of a 'history of ideas,' see Bevir, 1999.) Perhaps the impression of paradox can be diminished by pointing out that, as histories go, the history of linguistics must be either fairly short or else extremely long, depending on what is taken to count as linguistics. Since the term *linguistics* itself is a modern coinage, and hardly a decade passes without different theorists redefining it to suit their own academic agenda, it is hardly surprising that agreement is hard to come by.

Commenting on "the lack of a collectively assumed history of linguistic science," Auroux and Kouloughli (1991) contrast this situation with that obtaining in the natural sciences and castigate linguists for "clinging to the silly strategy of so-called 'scientific breaks.' The assumption made by some linguists that scientific thought about language begins with the work of their immediate Master, if not with their own, is "all the more derisory as there is no real consensus as to the contents and methods of the discipline."

Some might regard this as a harsh judgment, but it points to the reasons for preferring to speak here of a history not of linguistics, but of linguistic thought: 'linguistic thought' being understood to refer to

the detailed pursuit of general questions relating to language and languages. Even then, the notion of 'history' is problematic, not only because many texts that may have dealt with such questions are now lost, but also because the continuity supposedly linking such inquiries across time is, to say the least, often dubious. Furthermore, in the period this article covers, the key questions are often raised by philosophers, not by grammarians or language teachers; so it becomes difficult to disentangle anything that could reasonably be identified as an independent history of linguistics. With these misgivings duly stated, however, it is not impossible to pick out in the Western tradition a series of observations and discussions that connect thinking about linguistic topics across the centuries, even if the connection is to some extent a retrospective illusion of hindsight.

Social Background

Before attempting any 'historical' exposition even in this limited sense, it is relevant to draw attention to certain social factors that shape linguistic inquiry throughout most of the time span under consideration. For the most part, a historian has no option but to deal with *written* texts (see below): we are very poorly informed about the view of language(s) prevalent among those sections of the population of Europe who did not have the benefits (and disadvantages) of literacy. Another factor to be taken into account is that the spoken and written language of paramount importance in Europe for centuries was Latin. It provided a universal lingua franca among the educated classes, a knowledge of Latin being essential for those pursuing any kind of public career, whether educational, legal, administrative, or ecclesiastical. Consequently, it is Latin that tends to be the model language that is referred to tacitly or overtly in many linguistic discussions. A third consideration is that one particular Latin text, the Vulgate, was regarded as supremely authoritative and as supplying divinely inspired answers to certain basic linguistic questions. Anyone who loses sight of these three factors will be hard put to understand either the achievements or the limitations of Western linguistic thought before 1800.

A taken-for-granted knowledge of the Latin language became the basis for most intellectual forays into linguistic topics from the fall of the Roman Empire to the Renaissance. But the disintegration of the Roman Empire was matched by a disintegration of Latin, giving rise to the birth of the Romance languages. By the 9th century, it is clear that Latin was neither spoken nor understood by the masses (Strasburg Oaths, 842). That divorce between the Latin-based thinking of the intellectual minority and the incomprehension of the majority had profound consequences. It was the basis, eventually, for the rejection of the Pope's authority by Henry VIII (1491–1597), who established the rival Church of England. It led similarly to the German challenge to papal authority led by Martin Luther (1483–1546). Both rebellions were manifestations of the collapse of the European feudal system and the emergence of the modern nation-state.

By this time, a profound political change had overtaken thinking about language, reflecting a new view of society. What emerged was the idea that a language was in some sense the expression not of universal operations of the mind, but of the unique individuality of a particular nation.

Even so, there is a perspective from which linguistic thought in the Western tradition, both pre-Renaissance and post-Renaissance, may be viewed as a continuing search for answers to quite a small number of basic questions. It therefore seems sensible to present any historical account in terms of these topics, rather than the usual listing of works and authors, determined simply by chronology, that we find in conventional treatments of the subject. Their chronology often seems to assume that the mere succession of predecessors and successors in itself constitutes history and that it falls conveniently into 'periods' during which a certain consensus of ideas prevailed. This is far from being the case.

The six topics selected for attention in the following sections – the relationship between speech and writing, theories of form and meaning, the problem of truth, concepts of grammar, the relationship between language and Nature, and speculations about linguistic origins – crop up time and again in the Western tradition. It hardly needs pointing out that they interrelate in various ways. Some remain a constant focus of attention. Others emerge and re-emerge at intervals. Some were assumed to have been settled long ago and thus lie dormant for centuries. The present article tracks the more important positions down to the end of the 18th century. For later developments, *see* **Modern Linguistics: 1800 to the Present Day.**

Most of the key questions were first raised in ancient Greece. Classicists often tell us that the Greeks were the first to recognize language as the distinctive characteristic of *Homo sapiens*. However, this claim does not stand up to serious examination. What the Greeks saw as characteristic of the human being and human potential was *logos* (rationality). The power of speech was only one manifestation of *logos*, and Greek discussions of language tended to take this for granted.

Greek attitudes to language were profoundly ethnocentric. Peoples who did not speak or understand Greek were 'barbarians.' This conception parallels the Greek view of politics, in which slaves (often foreign captives or their descendants) had no rights as human beings. The Romans had a somewhat different view, because in their world many of the slaves were Greeks. Furthermore, many educated Romans were bilingual in Greek and Latin. Quintilian (c.35–96 A.D.) even discusses whether it is better that a child should be taught Greek first and Latin later, or the other way round.

Within the Greek-speaking world, there was great regard for two kinds of linguistic activity: poetry and public speaking. To the poets, and to Homer in particular, the Greeks owed a sense of their own identity as a people; while effective public speaking (taught professionally by rhetoricians) was a vital mechanism of government in the ancient city-states, as well as being essential to the political system known as 'democracy.' The first major challenge to traditional Greek attitudes toward poetry and rhetoric arose with the teachings of Socrates (469–399 B.C.) and Plato (427–347 B.C.). This is also where serious general questions about language are first raised.

Speech, Writing, and Scriptism

How is writing related to speech? This question takes pride of place, because the answer to it underpins the answers to so many others. All the topics that this article deals with have to be understood as topics raised within the context of a literate society, even if large percentages of the population were at various times illiterate or only minimally literate. So the question of the relationship between speech and writing immediately has profound social and political implications. It goes to the heart of the way a society is run and by whom, and this in turn determines who is raising the questions. We are dealing here with the public self-understanding of literate societies.

Plato's dialogue *Cratylus* is the earliest text of any length that has come down to us concerning explicitly linguistic topics. It was probably composed about 359/358 BC. At that time, Greece was still going through the long-drawn-out transition from a preliterate to a literate society, and it is significant that Plato, one of the most powerful thinkers of his own or any other age, was a skeptic about writing. He regarded with suspicion the claims made on behalf of this 'new' technology; for that, in effect, is what writing was in Greece during his lifetime. (See Harris, 1989 and Thomas, 1992 on literacy in ancient Greece.) All Greek thinking about language was colored by this transition, as the earliest Greek traditions (in particular those associated with Homer and the poets) dated from the antecedent culture of oral transmission (Havelock, 1982).

Plato's skepticism about writing does not come to the surface in *Cratylus*, but is quite explicit in his *Letters*. His chief complaint about writing, to put it anachronistically in modern terms, is this: even when writing specifically attempts to record what was originally said, the written form *decontextualizes* speech. Hence, it gives rise to false interpretations. No serious intellectual, according to Plato, would attempt to put down his most important ideas definitively in writing: that would be an act of irresponsibility. There is a moral judgment here, rarely recognized in mainstream histories of linguistics.

Why did Plato take this view? Part of the answer is that Plato's own teacher, Socrates, the most formidable intellect of his time, committed nothing to writing. He conducted oral debates in public on various topics with a variety of opponents, but often left both opponents and onlookers to draw their own conclusions. Another part of the answer is that Greek writing was alphabetic. Its basic elements were individual letters (*grammata*, a connection surviving in the modern term *grammar*), whose particular shapes were devoid of any linguistic significance. Thus (Greek) writing could be seen as divorced from ideas: the sequence of letters represented merely the external, superficial form of the spoken word, a lifeless shell. Herein lies the ultimate source of the profound difference between Western linguistic thought and Eastern linguistic thought (the scripts of China and Japan being nonalphabetic).

One of the ironies of Plato's legacy is that, in spite of his skepticism about writing, he left an important corpus of written texts for later generations to study. But it is no coincidence that many of these texts are left in dialogue form, for this form comes closest to approximating the cut-and-thrust of face-to-face debate. Plato's view of the relationship between speech and writing was based on the assumption that language in its 'natural' form is a live oral exchange between one individual and another. This notion reemerges with the thinking of Marshall McLuhan and other modern theorists for whom both writing and the mass media are seen as artificial perversions of a more fundamental form of linguistic communication.

In ancient Greece, the capitulation to the new technology is already evident in the work of Plato's most illustrious pupil, Aristotle (384–322 B.C.). Aristotle had evidently decided to yield to *force majeure*, so he never raises any penetrating questions about the relationship between speech and writing. He prefers

to treat speech and writing, for all practical and philosophical purposes, as equipollent modes of expressing thought.

Aristotle is sometimes said to have left no general treatise on language or languages (even though he wrote on rhetoric), and the lacuna has been lamented. This is a short-sighted judgment, because Aristotle's philosophy of language is embodied in considerable detail in what posterity regards with one accord as his pioneering texts on logic. Aristotle the logician is Aristotle the linguist. What Aristotle the logician seeks is a perspective on language that transcends particular languages. The crowning achievement of Aristotelian 'general linguistics' is the syllogism, because it works in Greek, or Latin, or Persian, or any other language you might be acquainted with. Plato, although in some respects a more profound thinker than his pupil, never managed to get as far as detecting the semantic pattern that underlies the connection among (1) 'All men are mortal,' (2) 'Socrates is a man,' and (3) 'Socrates is mortal.'

Thus, it suits Aristotle to adopt a rather simplistic view of the relationship between speech and writing. (So simplistic that it is in retrospect difficult to imagine that Aristotle himself could have given it much credence.) It is summarized at the beginning of *De Interpretatione*. Here we are told that

> Sounds produced by the voice are symbols of affections of the soul, and writing is a symbol of vocal sounds. And just as letters are not the same for all men, sounds are not the same either, although the affections directly expressed by these indications are the same for everyone, as are the things of which these impressions are images.

This single passage projects answers to a whole range of controversial questions. Aristotle assumes that the external world is the same for all observers and that observers' perceptions of this world are, for all practical purposes, identical. This approach, it need hardly be said, begs most of the central issues about language that are worth raising, but it was extremely influential throughout Western tradition.

Psychologically, Aristotle presupposes that communication is telementational: language exists to 'convey' thoughts from the mind of one person to the mind of another. But this can only be done insofar as words are associated with the same thoughts in both minds. That is the role of convention, as Aristotle sees it: to establish in a person's mind the connections between words and thoughts. Speech produces symbols of affections of the soul, whereas these affections themselves are not symbols, but likenesses of things in the external world. (On Aristotle's use of the term *symbolon,* see below.) Thus the chain connecting words to the world is divided by Aristotle into two sections. There is a section of natural, universal processes, linking the world through our senses to our mental representations of it; and there is a section of conventional, nonuniversal processes linking mental representations to language.

After Aristotle, no one in antiquity seriously questioned his disingenuous doctrine concerning the relationship between speech and writing. The Stoics, according to Diogenes Laertius (3rd century A.D.), were content to regard the elements (*stoicheia*) of language as being the 24 letters (i.e., of the Greek alphabet). However, he adds, the term 'letter' (*gramma*) has three meanings: a particular speech sound, the corresponding written symbol, or the corresponding name (e.g., *alpha*). Why the Stoics did not therefore introduce separate terms to distinguish these three items Diogenes does not explain, but the fact that they did not might be seen as pointing to a serious distortion in their way of looking at language. It is essentially scriptist – based on the linguistic biases of a literate society, in which only the views and preoccupations of the literate are deemed worthy of consideration – and for all such purposes it is assumed that speech can be 'reduced' to writing.

Given the prevalent scriptism of thinking about language in antiquity, what happened, inevitably, was that the structure of writing (in this instance, alphabetic) was projected back upon speech. That blocked the study of phonetics for more than a thousand years and is still evident today. (The so-called International Phonetic Alphabet is just one example. For a more detailed examination of scriptism in modern linguistics, see Linell, 2005.)

Various long-term consequences of these scriptist assumptions are worth mentioning here. One is that theorists often assume they can discuss words and sentences simply by citing their written form. The question of whether the written form actually corresponds to the spoken form – and, if so, how – is never allowed to arise. In short, speech is treated as if it were a spoken form of writing (or would be, if only it could). In the Middle Ages scriptist assumptions prevailed without question: the treatises of the modistic grammarians (see below) deliberately ignore the study of spoken language. As far as they are concerned, the sounds produced when one speaker speaks to another are of no consequence. This conveniently dispenses the *modistae* from considering any aspects of language that are not manifested in writing.

One secondary consequence is that orthographic criteria are sometimes invoked in the determination of linguistic units. A classic example in the 17th

century is the Port Royal definition of a word, which is said to be *ce qui se prononce à part, & s'écrit à part*. The latter part of this definition alludes naively to the rather late orthographic practice of leaving spaces between grammatical units in written texts. A more pervasive manifestation in modern times is the adoption of 'alphabetical order' in dictionaries. Another is the belief of many Europeans that their own name is a written form. Thus they will go to the trouble of pointing out to others that the spelling is *Anne*, not *Ann*. (In speech, it makes no difference.)

More generally, at the macrosocial level, scriptism is institutionalized in the way Western societies insist on having agreements 'put in writing' and 'signed' (i.e., validated by the personal signature appended to a document) if they are to have any legal validity. Literacy has come to be accepted as the foundation of all forms of education. The study of written texts was already the basis of the 'seven liberal arts' taught in medieval universities. In these various ways, Western linguistic thought over the long term has been continuously in thrall to the long-entrenched prestige of writing that originated in antiquity.

Form and Meaning

Given a scriptist conception of the elements of speech (i.e., as individual discrete segments of articulated sound corresponding to alphabetic letters, and linearly concatenated), the following questions immediately arise. How are these elements combined to form meaningful linguistic signs? What determines the meaning of these combinations?

Ostensibly, Plato's dialogue *Cratylus* records a curious debate between Cratylus and Hermogenes as to whether names are natural or not. According to Cratylus, "everything has a right name of its own, which comes by nature," and this "inherent correctness" is "the same for all men, both Greeks and barbarians." By contrast, according to Hermogenes, there is no "correctness of names other than convention and agreement." In short, "whatever name you give to a thing is its right name": "no name belongs to any thing by nature, but only by the habit and custom of those who employ it and who established the usage."

One idea examined in *Cratylus* is that spoken forms have a mimetic motivation: that is, the sounds making up a word reflect its meaning in some way or other. For example, the consonant *r*, being produced with a rapid movement of the tongue, is suited to expressing motion: it occurs in Greek words for 'flow', 'current', 'trembling', and 'run'. The vowel *o*, made by rounding the lips, expresses circularity and thus occurs in the word for 'round'. And so on. This notion that the form of a word imitates that which the word designates long survived antiquity: it turns up again in the 18th century; for example, in Leibniz (1646–1716), de Brosses (1709–1777), and Court de Gébelin (1728–1784).

The opposing point of view, often known as 'conventionalism' – or, since Saussure (1857–1913), 'arbitrariness' – holds that there is no such connection between form and meaning (onomatopoeia – for example, the word *cuckoo* supposedly being an imitation of the cuckoo's call – being regarded as a marginal exception).

In *Cratylus*, Socrates mediates the debate about form and meaning. By a series of shrewd questions, he maneuvers both parties into adopting apparently absurd positions. The implausibility of some of the etymologies selected for discussion has led some scholars to suppose that this is a satirical attack on the Greek fondness for etymological speculation. But it seems unlikely that a mind as penetrating as Plato's would have thought it worth devoting a whole dialogue to such a trivial purpose. More probably, the serious point of the dialogue should be seen as emerging when Socrates raises the question of what it is to tell the truth. For the pursuit of truth was the fundamental purpose of Plato's philosophy, and the form of words is by no means irrelevant to this goal (see below).

Aristotle, in the passage already cited, proposes a different approach to the relationship between form and meaning. It is, he claims, a 'symbolic' relationship, but what exactly he means by this is controversial. In the Greece of his day, a *symbolon* was a token (often a shard or piece of bone) broken in two, one half being retained by each of the parties to a transaction or commercial agreement. Aristotle seems to use the term metaphorically with respect to language. In that case, its significance would lie in the exact fit between the two halves (i.e., form and meaning) of the *symbolon* (word) when put together. If that is the correct interpretation, it becomes evident that for Aristotle the bond between form and meaning rests not on any resemblance between the linguistic form and what it stands for, nor on any other intrinsic suitability to represent the thing represented, but purely on the agreement between speaker and hearer concerning their particular linguistic transaction. In short, the meaning is imposed on the form psychologically by those making the communicational contract.

This is a position which can be read as supporting Hermogenes in Plato's dialogue. It is noteworthy that there is no appeal here by Aristotle to any set of overt or public conventions for determining the relationship between form and meaning. In this respect, the relationship is regarded as 'unregulated' in much the same sense as in modern integrationist theory

(*see* **Integrational Linguistics and Semiology**), whereas the more orthodox view since Aristotle's day has been to treat the connection between form and meaning as determined by the public linguistic 'code' constituted by whatever language (Greek, Latin, English, etc.) the interlocutors are speaking.

From a code-based perspective, the linguistic individualism of Hermogenes seems to be ridiculous, anticipating Humpty Dumpty in Lewis Carroll's *Through the looking glass*, who claims to be able to use any word in any sense he chooses.

A position somewhere in between radical individualism and code-based linguistic orthodoxy is taken in the late 17th century by the English empiricist philosopher, John Locke (1632–1704). Locke elaborates a psychocentric semantics, in which individuals are responsible for the meanings of the words they use. According to Locke, in his *Essay concerning human understanding*, words "in their primary or immediate signification" stand for nothing but ideas in the mind of their user. In short, language is not a direct reflection of reality, but a reflection of what people suppose reality to be. This undermines Aristotle's assumption that we all live in the same world, identically perceived by all its observers. Locke goes on to suggest that linguistic communication is something of an illusion. Men suppose that their words are "marks of the ideas in the minds also of other men, with whom they communicate," since without that correspondence communication would be impossible. Men also suppose that their words "stand for the reality of things."

The point Locke is making alludes obliquely to a long-running dispute in the Western tradition between 'realists' and 'nominalists.' Realists are traditionally taken to be those who hold that there exists a reality independent of human perceptions or beliefs, and that language is based ultimately on this independent reality. (This conviction lies at the heart of 'reocentric' theories of meaning: roughly, the meaning of the word *copper* is based on the 'real' existence of the metal copper, it being assumed that the metal exists anyway, regardless of what it is called or whether it is recognized as such.) Nominalists, on the other hand, are those who hold that there is no ground for supposing that anything exists independently of its recognition in actual examples and that meaning depends on what such examples are called in particular cases. Both doctrines are sometimes opposed to 'conceptualism.' The latter terms covers a miscellany of positions in which emphasis is placed on the alleged capacity of the human mind to form abstract concepts independently of whatever exists or is said to exist. But all three labels need to be taken *cum grano salis*. Their interpretation depends very much on the view of the interpreter. Thus, for example, Peter Abelard (1079–1142), the leading Scholastic philosopher of his day, has variously been classified as a realist, a nominalist, and a conceptualist as well. The linguistic issue was nevertheless of some relevance to theological disputes in the Middle Ages (for instance, concerning the nature of the Eucharist in the Christian church, and descriptions of God and His attributes).

Language and Truth

The question of the relationship between form and meaning in turn gives rise to a problem about truth. According to the traditional Western view, which again goes back to Plato and Aristotle, language is doubly imbricated in the pursuit of truth. For (1) until an explicit statement is made (e.g., 'Homer is alive' or 'Homer is dead'), no question of truth or falsehood arises, and (2) what we take a statement to be asserting depends on how we understand whatever names it deploys (e.g., *Homer*). The relationship between forms and meanings is crucial here. If names are no more than conventional designations, the truth of the matter seems to be tied to whatever is the general opinion. But suppose general opinion is mistaken (e.g., suppose there was no such person as Homer). This is where the issue of the mere 'conventionality' of names begins to bite in a philosophically disturbing manner. It is also the reason why the debate about proper names and truth has remained on the philosophical agenda ever since.

As conducted in *Cratylus*, the debate is not confined to what would now be called 'proper' names. Nor does it reach a very satisfactory outcome. Socrates seems to be unable to make up his mind, except to conclude that "surely no man of sense can put himself and his soul under the control of names, and trust in names and their makers to the point of affirming that he knows anything." But the debate also links up more immediately with the Platonic theory of Forms, according to which things on Earth are no more than imperfect copies of sempiternal exemplars existing in a timeless realm of their own. This version of realism has far-reaching semantic implications. In modern times they extend as far as the neo-Platonist semantics of Frege (1848–1925) and his followers.

In Plato's dialogues, Socrates appears anxious to maintain a thesis about the determinacy of meaning: we could not describe even the inconstancies of things if the concepts employed in these descriptions were themselves inconstant. This argument seems to be implicitly accepted by Aristotle when he formulates what is now referred to as the 'correspondence theory' of truth. What Aristotle says in his *Metaphysics* is

that truth is "to say of what is that it is, or of what is not that it is not." Although this reocentric formulation seems unexceptionable as far as it goes, it dodges the crucial questions of how we can tell what 'is' or how we can tell whether what might be said is said 'of it.'

Aristotle's lasting contribution to Western linguistic thought lies in proposing that, although different languages have different words, they all use similar types of word combinations to express similar patterns of ideas. That, however, is not how Aristotle himself would have seen it. He thought he was laying bare not a mere linguistic coincidence, but a universal truth about human reason. How did he come to this view? What allowed him to reach it was his adherence to a particular version of the Hermogenean doctrine of 'conventionalism.' As is clear from the passage from *De Interpretatione* cited above, Aristotle maintained that although different word conventions may be in use in different languages, the things to which words refer do not differ. Nor do the concepts that human beings express by means of these words. Given these assumptions, it followed that all languages, however superficially diverse in their forms of expression, must ultimately be reflections of the same underlying reality, and hence human reason, as expressed in language, must be everywhere the same.

This Aristotelian view was to dominate European thinking about language for centuries to come. Words would be regarded merely as vocal labels attached to a universal set of things, properties, processes, and relations existing independently in the world about us. That view, in various sophisticated versions, is still alive in modern linguistics. In its most banal form, it is reflected in the modern bilingual dictionary, which assures us that what is meant in English by the word *dog* is also what is meant in French by the word *chien*. The equivalence is allegedly guaranteed by the fact that dogs are the same on both sides of the straits of Dover. So from 'All dogs are mortal' and 'Rover is a dog,' it follows that 'Rover is mortal' both in England and in France. Or, if we prefer the French version, 'Tous les chiens sont mortels, 'Rover est un chien,' and 'Rover est mortel.'

But how do we know that a community has got its labeling of reality correct in the first place? The argument about forms and meanings in *Cratylus* anticipates in some respects the kind of skepticism about language that Francis Bacon (1561–1626) made explicit many centuries later in his condemnation of *idola fori*. These 'idols,' according to Bacon, are misconceptions that language imposes on the human mind: they are "false appearances that are imposed upon us by words." In his *Novum Organum* (1620), Bacon shrewdly observes, in protest against the view that had prevailed ever since Aristotle, that although we believe that our words are governed by reason, it is nevertheless true that words "react on the understanding." He argues that words usually reflect the understanding of the uneducated and draw distinctions that are easy for the uneducated to grasp. So that whenever more careful analysis or more accurate observation are required to "suit the true divisions of nature," words prove to be an obstacle and impede changes in ways of thinking.

Bacon is not very specific about the "false appearances" that can be created by words or how they arise, but presumably they would include the case of words 'standing for' things that do not in reality exist. Thus, for instance, if there are no such animals as unicorns, the word *unicorn* exemplifies a verbal deception of this order, inasmuch as the existence of the word might be taken to imply the existence of the animal. A more convincing modern example might be the word *mind*: there is much talk about our minds and how they work, but – as behaviorists would insist – that is no guarantee whatsoever that we have minds (as distinct from brains) at all. The only remedy for "false appearances" that Bacon suggests is always to define our terms before entering into "controversies and disputations." But it is difficult to see how doing that would help very much if all parties were deceived by the same "false appearances."

When a reocentric view of meaning is combined with Aristotelian conventionalism, we reach the conclusion that the meaning of a word is 'conventionally' determined by what the word 'stands for', e.g., *copper* being the conventional name (in one language or linguistic community) for the metal copper. It then seems to be illusory to look for some underlying universal reason why copper is called *copper*. That would be an *ignis fatuus*. The only valid question(s) would be how, historically, copper came to be called *copper* in English, *cuivre* in French, etc. But that reformulation already presupposes that it is indeed the 'same' metal that is called *copper* in English, *cuivre* in French, and so on. In short, reocentric semantics generates problems to which Western linguistic thought never supplied any but circular answers.

Doubtless that lacuna was obscured by the way biblical wisdom on the subject seemed to support a straightforward reocentric answer to questions of meaning. The orthodox Christian account of language was based on a well-known passage in the Book of Genesis:

> And out of the ground the Lord God formed every beast of the field, and every fowl of the air; and brought them unto Adam to see what he would call them: and

> whatsoever Adam called every living creature, that was the name thereof. And Adam gave names to all cattle, and to the fowl of the air, and to every beast of the field [. . .]. (Genesis 2:19–20, King James version).

As it happens, this account coincides with Aristotle's assumptions in several important respects. First, there is no question of Adam being asked to name creatures that do not exist: their existence is logically prior to the act of naming. Second, the act of naming is what establishes the relationship between form and meaning. Third, although we are not told why Adam chose any given name, God never rejected any of Adam's names as inappropriate.

This last point could be construed in two ways. One interpretation would be that it did not matter what name Adam came up with. (This would endorse the conventionalist view of nomenclature: here Adam is seen as a Hermogenes.) An alternative interpretation would be that Adam 'got the names right.' By uncorrupted intuition, he saw which names were appropriate to the nature of the animal in question. (Here Adam is seen as a Cratylus, who can somehow sense the 'natural' name that a creature ought to have.) Later it was often assumed that the second interpretation was correct, because the account in Genesis describes Adam's nomenclatorial feats as taking place before the Fall. Here we witness a classic example of how linguistic questions in the Western tradition hinged for centuries on religious beliefs.

Grammar

If the sounds of speech are conceived as elements linearly combined to form meaningful words, the next obvious question would seem to be: how are these meaningful units themselves combined? This question falls under the rubric of what was later in the Western tradition called 'grammar.' But, although the Greeks are often credited by historians with initiating grammatical studies, the modern term does not entirely coincide with what the Greeks regarded as *grammatike*.

Although it seemed obvious enough to Greek thinkers that, both in speech and writing, words have to be combined sequentially in order to express statements, syntax did not attract a great deal of interest or attention in the Classical period.

At the beginning of *De Interpretatione,* Aristotle insists on the importance of distinguishing the forms of combination that can be observed in language, but this is because it is implicated in questions of truth and falsity:

> Just as some thoughts in the mind are neither true nor false, while others are necessarily one or the other, so it is also with spoken sounds. For falsity and truth have to do with combination and separation. Thus names and predicates by themselves – for instance 'man' or 'white' when standing alone – are like thoughts that are without combination or separation; for thus far they are neither true nor false.

Aristotle needs this distinction to establish for logical purposes the difference between sentences and statements; but once this is done he does not pursue the topic of combination further.

There is no syntax either in the earliest Greek grammatical treatise to have survived, which is attributed to Dionysius Thrax (see below): it lists the parts of speech but does not attempt to give any indication of how to construct a sentence. This lacuna is of some significance. It reflects a view of language in which knowing how to put words together in order to express a coherent proposition is not so much a linguistic ability as an exercise of reason.

The Greek and Roman systems of education were eventually professionalized in a way that separated the special study of (1) the rational use of language from (2) the persuasive use of language and (3) the correct use of language. (The physiological implementation of language was not even deemed worthy of recognition. If it had been, Western linguistic thought might have developed along quite different lines.) These three provinces were professionally allocated to the logician, the rhetorician, and the grammarian, respectively. That tripartite division lasted into the European Middle Ages, where logic, rhetoric, and grammar became the so-called *trivium* of the standard university syllabus. (The corresponding *quadrivium* comprised arithmetic, geometry, astronomy, and music.) Roughly speaking, therefore, the *trivium* was devoted to words, whereas the *quadrivium* was devoted to numbers (both astronomy and music being seen as applications of mathematics).

Grammar was a later development than either rhetoric or logic. According to Robins (1966), who traces the development of the 'parts of speech' system from the earliest times, the Greeks could not have developed the basis for a fully explicit combinatorial analysis of the sentence until the 2nd century B.C.: Plato seemed to recognize only two parts of speech, Aristotle three, and the early Stoics four. The first surviving account of what was to become the canonical eight parts of speech for later European grammarians is attributed to Dionysius Thrax (c.170–c.90 B.C.). He was a pupil of the Alexandrian scholar Aristarchus (c. 216–144 B.C.). Whether Dionysius wrote the treatise *Techne Grammatike* that traditionally bears his name is uncertain: according to some scholars, the text we have is a much later compilation. Be that as it may, its priority seems to be to identify and name the basic units that learners (of Greek) must grasp.

(Dionysius did not claim, as far as we know, that it applied to all languages. But it is relevant to note that he lived in a period when the teaching of Greek to non-Greek speakers, as a consequence of Alexander's conquests, had assumed a certain importance.)

The analysis Dionysius gives is interesting for various reasons. It reflects the Greek tendency – both as regards language and most other matters – to equate 'explanation' with resolving a complex into its ultimate constituents. The atomism of Democritus (c.470–c.370 B.C.) and his followers is the most conspicuous example of this tendency in the study of the physical world. In late antiquity we find one of the most prestigious Latin grammarians, Priscian (see below), explicitly appealing to the analogy between atoms and speech sounds. Applied to language, this can yield the kind of analysis that we find in Dionysius, who, although ignoring syntax, provides detailed taxonomies for (1) individual speech sounds, (2) syllables, and (3) words, together with brief remarks about accent and punctuation, as if that were all the grammarian needed.

However, this sits ill with his own definition of grammar, which is "the practical knowledge of the general usages of poets and prose writers." Furthermore, according to Dionysius, grammar divides into six parts: reading aloud, with due regard to the prosodic marks; explanation of poetic tropes in the works; elucidation of difficult words and narratives; discovery of etymologies; establishing analogies; and, finally, literary appreciation, which, Dionysius adds, is the finest part of grammar. It need hardly be said that this definition would not be endorsed by any modern grammarian.

The fifth of Dionysius' six branches – establishing analogies – calls for comment, since it reflects a debate about language regarded as important in the ancient world. Some teachers (the 'analogists') seem to have emphasized the regularity of linguistic structures, while their rivals (the 'anomalists') emphasized the frequency of irregularities. Translated into modern terms, the debate seems of little interest. Analogists would point out that the great majority of English nouns form a plural combinatorially by adding *-s* (*cat*, *cats*; *dog*, *dogs*). Anomalists, one supposes, would counter this by pointing out exceptions (*man*, *men*; *woman*, *women*).

What lay behind this apparently futile kind of controversy it is difficult to tell. The Stoics were regarded as champions of the anomalist position. According to the Roman scholar Varro (116–27 B.C.), the Stoic philosopher Chrysippus (c. 280–207 B.C.) wrote three books to demonstrate "that like things are denoted by unlike words and that unlike things are denoted by like words." Why would he have done that? Presumably because it served to defend the theoretical position that language is not 'rational' in the sense of being derived directly and systematically from the regularities observable in the extralinguistic world. However, it is also likely that the controversy between analogists and anomalists engaged pedagogic issues concerning rival teaching methods, about which little is known.

Grammar as Dionysius presents it has very little to do with examining the systematic articulation of rational argument, or with the techniques of verbal persuasion, but is oriented primarily toward the study of literary texts, with a heavy leaning in the direction of elementary teaching requirements. Both in Dionysius's definition of grammar and elsewhere in his treatise, we find clear confirmation that linguistic inquiry is now geared to the educational program of a literate society. The very name of his discipline is derived from Greek *gramma,* 'letter'. His classification of linguistic elements (*stoicheia*) at the lowest level is, like that of the Stoics, overtly based on the letters of the Greek alphabet: he seems to assume that these 24 minimal orthographic units automatically correspond to 24 such phonetic units. There is no attempt to demonstrate that this is actually the case.

One combinatorial study that Dionysius neglected (i.e., Greek syntax) was given its first detailed examination some centuries after Dionysius's death by the Alexandrian grammarian Apollonius Dyscolus (2nd century A.D.). Although of the analogist persuasion, Apollonius was certainly interested in the question of why syntactic anomalies exist. The study of Latin syntax had to wait some centuries yet for any comparable treatment. It eventually came with the work of Priscian (Priscianus Caesariensis, fl. 500 A.D.) who taught Latin in Constantinople, then the (mainly Greek-speaking) capital of the Byzantine Empire. His *Institutiones grammaticae* was the most comprehensive grammar of Latin produced in the ancient world, and its last two books dealt with syntax in a manner evidently inspired by Apollonius's exposition of Greek.

Priscian's account of Latin syntax in turn provided the point of departure for the most original approach to the subject, which was developed by the modistic or 'speculative' grammarians of the later Middle Ages. They included Boethius of Dacia, Albertus, Siger de Courtrai, and Thomas of Erfurt, all of whom were active during the period from 1270 to 1310. The term *modistae* reflects the fact that their treatises were usually said to be about the *modi significandi* or 'modes of signifying'. The term 'speculative' grammarians is indicative of their view of language as a mirror (*speculum*) of the world as

reflected in the human mind. Their grammars are not intended for practical teaching purposes, although they are heavily indebted to Priscian and other ancient grammarians for their basic view of the structure of Latin. It does not occur to them that Latin may not be a typical language: they simply assume this to be the case.

However, the *modistae* seem to recognize that in antiquity we never find a clear analysis of *how* a word is capable of 'standing for' some nonlinguistic entity. The notion of 'naming' something (e.g., *Socrates* being 'the name of' a particular person, or *aes* being the name of a certain metal) is just taken for granted: names are part of the linguistic equipment that a language supplies. The same goes for all the parts of speech. The *modistae* realize that these unexplicated assumptions are quite inadequate for any deeper comprehension of language. They seek to explain the rationale of grammar by invoking a set of distinctions between various 'modes of signifying'; for example, 'active' versus 'passive,' 'essential' versus 'accidental.' These in turn relate psychologically to different 'modes of understanding,' as well as objectively to different 'modes of being.' In this way an elaborate organization is built up of the ways in which words relate to the world via the operations of the mind. The active mode of signifying is that by which a given form signifies the property of the thing it designates, while the passive mode of signifying is that by which the property of the thing in question is signified by the form of the word. A linguistic sign both signifies and 'consignifies.' In virtue of its consignification, the sign functions as a part of speech, and this determines its combinatorial possibilities.

Some modistic explanations of grammatical features strain credulity. For example, Thomas of Erfurt accounts for the gender of Latin nouns by claiming that the masculine gender signifies the thing designated by means of the property of acting, while the feminine gender signifies the thing designated by means of the property of being acted upon. This seems hard to reconcile with some of his own examples; e.g., the Latin nouns *lapis* (masculine) and *petra* (feminine), both meaning 'stone'.

Modistic thinking about language is aprioristic to a degree. The notion that certain hypotheses might require testing against observation of language in use is entirely absent from their work. The ultimate goal is defined within the parameters of medieval Catholicism: to demonstrate how God designed language in such a way as to permit human beings to obtain a certain (partial) grasp of the wonders of His creation. By the time of the Renaissance the modistic approach to grammar was already abandoned.

The most famous grammar of the post-Renaissance period, the *Grammaire générale et raisonnée* (1660) of Antoine Arnauld (1612–1694) and Claude Lancelot (1615–1695), otherwise known as the 'Port Royal grammar,' adopts an overtly pedagogical perspective on language and language learning, wedded to a simplistic theory of human psychology. For these authors, as for Aristotle, the basic function of language is telementational: it exists to 'convey' thoughts from the mind of one person to the mind of another. Its structure is therefore dependent on the thoughts to be conveyed:

> [...] men, having had need of signs in order to mark everything that occurs in their minds, also found it necessary to draw a most general distinction among words into those that signify the objects of thoughts and those that signify the form and manner or mode of our thoughts [...].

These mental distinctions, according to the Port Royal grammarians, constitute the foundation of grammar in all languages. There are, they claim, three basic operations of the human mind: conceiving, judging, and reasoning. Conceiving they describe as what happens when the mind simply contemplates things, either with or without the help of visual images. Judging is deciding that something conceived is, or is not, the case. Reasoning is using two judgments to arrive at a third.

On this slender basis they propose to explain all the traditional parts of speech: nouns, adjectives, pronouns, participles, prepositions, adverbs, verbs, conjunctions, and interjections. This leads them to some extraordinary conclusions. Perhaps the most striking is that there is only one 'true' verb; namely, the verb 'to be' in its third person singular present indicative form. (This conclusion is based on their view that the basic function of a verb ought to be to "mark the connection that we make in our minds between the two terms of a proposition.") Another is that the difference between nouns and adjectives is that nouns serve to designate the objects of our thoughts as "substances," whereas adjectives designate the objects of our thoughts as "accidents." The difference between substances and accidents is held to be that the former are conceived as existing independently, whereas the latter only as manifested in some substance. This in turn supposedly explains why adjectives 'need' the grammatical support of nouns, whereas nouns can 'stand alone' in discourse. The definite article causes them problems too. It 'ought' not to occur with a proper name, according to their 'rational' explanation of proper names. (Thus *London is a city*, but not *The London is a city*, because the proper name – *London* – already

sufficiently identifies the city in question.) But in some languages and in some instances, it is nevertheless customary to use the definite article with certain proper names. The authors of the Port Royal grammar recognize this and find themselves obliged to admit that "usage does not always agree with reason." But it does not occur to them to think that perhaps they are putting the cart before the horse throughout their enterprise by postulating a relationship in which thought processes dictate grammar, rather than grammar dictating thought processes. (For the latter view, *see* **Modern Linguistics: 1800 to the Present Day**.)

Language, Nature, and Science

Scriptist assumptions, combined with an 'Adamic' approach to language, eventually flowered in the attempt to construct a 'language of science' for physics, chemistry, geology, and similar investigations. That linguistic task was taken seriously in the 17th century by the 'experimental philosophers' who came together to set up such bodies as the Royal Society of London. One of these was John Wilkins (1641–1672). His *Essay towards a real character and a philosophical language* (1668) attempts to bypass speech altogether by relating written marks directly and reocentrically to existing things. In this way he hopes to provide a form of communication which will cut through all impediments to understanding offered by adopting established languages such as Greek, Latin, and English. These are seen as obstacles to human understanding. Bypassing them in favor of a more explicit 'philosophical' system of expression is proposed as a major advance both in human control over language and in the investigation of the natural world. What Wilkins is attempting is a practical linguistic solution to Bacon's problem of *idola fori* (see above). Wilkins recognizes the need to construct a new scientific language from first principles, free from the errors and obscurities that will inevitably have become embodied in the languages currently available for everyday discourse.

However, the way Wilkins set about his task is still essentially Aristotelian. He states his initial premise as follows:

> As men do generally agree in the same Principle of Reason, so do they likewise agree in the same *Internal Notion* or *Apprehension of things*.

This premise echoes Aristotle's assumption that "affections of the soul" are the same for everyone. Wilkins claims that it is by external expression of these internal notions that men "communicate their thoughts to one another," thus endorsing the Aristotelian view of communication as telementation. He tells his readers explicitly that the "conceit" that men have in their minds of a horse is the "notion or mental image" of that animal. Here we see the third component of Aristotle's doctrine: that affections of the soul are derived from external objects, which are the same for all observers. For Wilkins, names of things are "arbitrary sounds or words" that men have agreed on, "either casually or designedly," to express their mental notions. Still following Aristotle, Wilkins assumes that there is no 'natural' connection between the word and what it stands for. He argues that, if all this is so, it lies within our power to institute a universal system of communication by consent. This would liberate mankind from what he calls "that Curse in the Confusion of Tongues."

How can writing be liberated from its dependence on speech, and thus be equipped to serve as the basis for an international language of science? Wilkins's answer was the construction of a new writing system "that should not signifie *words*, but *things* and *notions*, and consequently might be legible by any nation in their own Tongue." In brief, Wilkins' project consisted in keeping the Aristotelian model, but promoting writing to the role traditionally played by speech. In this way, the written sign is brought into a direct, rather than an indirect, relationship to what it signifies.

Like other 17th-century thinkers, including Bacon, Wilkins regarded the case of Chinese as showing that, in principle, such a project was feasible; Chinese script being regarded as readable in various languages and thus providing a bridge between populations incapable of understanding one another's speech. However, in his view, all existing languages and writing systems were flawed, inasmuch as more than one meaning could be given to the same form, while different forms might have the same meaning. These imperfections would have to be eliminated in a rationally designed language of science.

For this purpose it was necessary first to draw up a systematic classification of everything known, set out in a series of tables, so that unambiguous signs could be allocated to each separate class of things. Wilkins attempted to do this. The problem with such a proposal is that it presupposes that a complete knowledge of Nature is already available: or if due allowance is to be made for a future expansion of knowledge, it must be so designed as to admit additions without upsetting the basic classification.

After Wilkins's death, the Royal Society set up a committee to improve his scheme. The committee never delivered its report, perhaps because of internal disagreements, but perhaps because its members came to realize the fundamental flaws in the thinking behind it.

Linguistic Origins

The account given in Genesis 2 (see above) continued to dominate thinking about the origin of language. It was supplemented by the story of the Tower of Babel in Genesis 11, which was taken as explaining why there were so many different and mutually incomprehensible languages in the world. This was a form of divine punishment, inflicted on mankind for presumption.

> And the whole earth was of one language, and of one speech. [...] And they said, 'Go to, let us build us a city and a tower, whose top may reach unto heaven. [...] And the Lord came down to see the city and the tower, which the children of men builded. And the Lord said, 'Behold, the people is one, and they have all one language; and this they begin to do: and now nothing will be restrained from them, which they have imagined to do. Go to, let us go down, and there confound their language, that they may not understand one another's speech.' So the Lord scattered them abroad from thence upon the face of all the earth: and they left off to build the city. (Genesis 11:1–9, King James version).

Since it was sacrilegious to question the authority of the Scriptures, these two stories between them imposed serious limitations on the scope of linguistic inquiry for generations after Jerome's translation had become the official Bible of the Christian church. It might seem odd at first sight that biblical translation was not itself regarded as a form of sacrilege (since the diversity of languages was evidently in accordance with the will of God and the act of translation might therefore be seen as a way of avoiding God's punishment). But bilingualism was such a conspicuous feature of Graeco-Roman culture that it would hardly have been feasible in Jerome's day to insist on a religious condemnation of translation as such. In any case, the translation of the Septuagint from Hebrew into Greek, according to tradition, dated back to the 3rd century B.C. and, in the conviction of Christian apologists, was divinely inspired.

Whatever the rationale, the European tradition inherited – and the Vulgate exemplified – a view of language in which it was taken for granted that it was possible in principle for translation to be practiced. This is an important assumption, since it leads directly to the that, in spite of superficial diversity, there may be – or must be – a common substratum that makes it possible to translate from one language into another. That was perfectly in accordance with the Babel story as reported in Genesis: for there what God did could be seen as simply scrambling the correlations between sounds and meanings. There is no suggestion in the Bible that, after the "confusion of tongues," some speakers could no longer recognize a brick as a brick or a spade as a spade. What they failed to recognize was the word for 'brick' and the word for 'spade.' So their ambitious building operation collapsed through a breakdown in communication, and not because their minds had been addled. Given this rationale, it was always possible that communication could be restored (i.e., by finding some way of linking up superficially diverse forms to a single underlying meaning). And that, precisely, was the concept and function of translation as envisaged throughout the history of Western education.

In the Greek world there was no traditional account of the origin and diversification of language as specific as that presented in the Bible. In *Cratylus*, vague reference is made to an original "name-maker" or "name-giver," supposedly responsible for coining the first words; but exactly who this person was is never explained. Nor did the Greeks have any traditional account of the diversification of languages or any notion of an ancestral language from which Greek might have descended.

The hypothesis that Latin was derived from Greek was not unknown in antiquity, but it gave rise to no systematic investigation of the way in which that linguistic process might have taken place. The attempt to 'explain' certain words by reference to other words, or older forms of the same word, is very ancient and appears already in Homer. (He connects the name *Odysseus* with verb forms meaning 'grieve' and 'hate'.) Greek and Roman grammarians treat such explanations as a branch of linguistic knowledge and place it under the rubric of etymology. Etymological studies were commonly supposed to be capable of revealing the truth (Greek *etymon*) about the things designated by the words thus explained.

In *Cratylus*, Socrates entertains the notion of linguistic change and suggests that over time word forms may have altered, thus concealing their original meaning. By the time of Varro, etymology has developed into a significant branch of learning, but is still unsystematic. For later generations, Varro's name became associated with the proposal of far-fetched hypotheses about the origins of words. He seemed to have thought that words were first "imposed on things" by human initiative, but that mistakes may have been made in the process. Thus, for instance, both the male and the female eagle are denoted in Latin by the same form *aquila*; whereas according to Varro the terms for male and female bird should be different. This implies a view of language according to which, originally at least, differences between word forms were intended to reflect differences in Nature.

In the later Middle Ages, the question of linguistic origins is taken up again, notably by Dante

(1261–1321). Like all his contemporaries, Dante accepts the biblical account. He also takes it for granted that the first language must have been Hebrew. But the most original strand in his thinking lies in his supposition that after the Tower of Babel three distinct varieties of language were introduced into Europe. These Dante identifies by reference to their word for 'yes.' This is perhaps the first example of the notion that comparative linguistic evidence provides a sound foundation for drawing conclusions about the linguistic past. Thus, as one enthusiastic modern commentator puts it, "from fundamentalist interpretation of the Bible he passes in a bound to a scientific recognition of the existence in Europe of the three groupings now identified as Germanic, Greek and Romance" (Elcock, 1960: 456). This somewhat overstates Dante's achievement as a linguist. However, he shows himself to be well aware of the dialectal divergence of the Italian peninsula in his own day, and counts at least 14 different dialects.

By the 18th century, the question of linguistic origins and the credibility of the biblical account has become controversial. Some writers are still reluctant to challenge the authority of the Bible. Others did not hesitate to put forward a 'natural' explanation of the origin of language, which dispenses with any act of divine intervention and seeks to explain the development of human speech in terms of the communicational needs of human beings in society. Authors who played a part in this debate include Mandeville (c.1670–1733), de Brosses (1709–1777), Condillac (1715–1780), Rousseau (1712–1788), Herder (1744–1803), Court de Gébelin (1728–1784), Voltaire (1694–1778), and other contributors to the *Encyclopédie*. The debate itself paved the way for a more empirical approach to questions of linguistic change and relationships between languages. (*See* **Modern Linguistics: 1800 to the Present Day.**)

Conclusion

Western linguistic thought before 1800 is mainly oriented toward providing validations for positions adopted in philosophy, or in pedagogic practice, or else in religious teaching based on the Bible. There is little or no conception of an independent scholarly inquiry into the whole gamut of known languages. That was to be the work of later generations. Although all the questions discussed above were considered at some time or other, it is worth emphasizing that at no point were they all considered systematically at one time by a single individual or school. That fragmentation is itself characteristic of Western linguistic thought during these centuries.

Western Sahara: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Western Sahara is a territory on the northwest coast of Africa bordered by Morocco (443 km), Mauritania (1561 km), and Algeria (42 km). It was administered by Spain until 1976 when Morocco annexed the northern two-thirds of the country (formerly called Spanish Sahara). Mauritania annexed the southern third of the country at the same time, but relinquished it after three years in 1979. After Mauritania's withdrawal, Morocco claimed and administered Western Sahara, the sovereignty of which remains unresolved.

Western Sahara, which has a total area of 266 000 square kilometers, consists mainly of low, flat desert with large areas of rocky or sandy surfaces rising to small mountains in the south and northeast. It has a population of 267 405 based on a 2004 estimate.

The main languages spoken are Hassaniya Arabic and Moroccan Arabic among the mainly Arab and Berber ethnic groups.

See also: Arabic; Berber; Mauritania: Language Situation; Morocco: Language Situation.

Westphal, Ernst Oswald Johannes (1919–1990)

G T Childs, Portland State University, Portland, OR

© 2006 Elsevier Ltd. All rights reserved.

Born in 1919 to Lutheran missionaries, Westphal learned the language of the mission station at Khalava of Vendaland in the Northern Transvaal (South Africa). Throughout his life he had a respect and fondness for the Venda culture, feelings he extended to other African groups. "He was deeply steeped in Venda culture, and in fact always claimed that he felt more at ease with Venda music – or with any African performing arts – than with those of Europe" (Rycroft, 1992: vii). Along with Venda he learned English, Afrikaans, and German as a child, and studied many of the major languages of southern Africa.

As was common at the time, Westphal remained something of a generalist and a (southern) Africanist, making significant contributions in both Khoisan and Bantu studies. Because his work was descriptive and in some sense pretheoretical, it has been plumbed for modern analyses. Westphal followed the lead of his mentor C. M. Doke in characterizing the languages he studied in their own terms rather than using prevailing European models (Gowlett, 1992). He was a careful worker, particularly in comparative work and reconstruction (Borland, 1992: 6). Perhaps his most widely known work surveys the Khoisan languages (Westphal, 1971), a group he felt did *not* form a genetic group.

Just as careful was his work in phonetics, particularly the study of tone. Westphal has been praised for his fine ear and the introduction of experimental techniques in phonetics. In 1952 he took "a long spell of arduous study leave … [in Angola, Botswana, and Namibia], equipped with an early Soundmirror tape recorder (using paper tape), powered by a cumbrous portable generator" (Rycroft, 1992: vii). Furthermore, he pioneered the use of computers in Bantu comparative studies (Borland, 1992).

Westphal studied under many of the early greats in African linguistics. He began his studies with C. M. Doke at the University of the Witwatersrand (Wits), where he earned his B.A. in phonetics, linguistics, and African languages in 1940, and his honors degree in African languages (Zulu and Southern Sotho) in 1941. At Wits he had the good fortune to learn phonetics from the only phonetician in South Africa, P. de V. Pienaar, which studies he later continued at the University of London. In 1942 he was appointed to a lectureship in African languages at Wits, which he held for five years.

The great Bantu comparativist, Malcolm Guthrie, recruited Westphal on a visit to South Africa for the School of Oriental and African Studies (SOAS), where he got to know A. N. Tucker and earned his Ph.D. under Guthrie in 1955. Because of his deep knowledge of Venda, Westphal was able to write his thesis 'The sentence in Venda' with himself as the sole informant (Rycroft, 1992: vii). At SOAS he was soon (1949) appointed a lecturer in Bantu languages, a position which he held until 1962, when he was appointed Chair of African Languages at the University of Cape Town, where he stayed until his 1984 retirement. Although not politically active, Westphal had "an innate sense of human justice"; he "was the first head of an African Language department who succeeded … in getting Black lecturers appointed

Whistled Speech and Whistled Languages

J Meyer, Institut des Sciences de l'Homme, Lyon, France

B Gautheron, University of Paris III, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Several populations all over the world have naturally developed a whistled form of their local language in response to isolated conditions in their everyday life.

Whistled speech is a system of communication based on whistles modulated according to features in common with the spoken equivalent. Therefore, it is a vehicle for articulated language in the true sense of the word.

The fact that the information is quite unintelligible to untrained speakers long made whistled languages objects of mystery, even if their existence was reported since the treaty of the Tao in Asia (6th century B.C.) and since the 14th century in the island of La Gomera (Canary Islands). It is also the reason why so few researchers became interested in this alternative way of transmitting messages in a linguistic attitude.

The first scientific studies concerned mainly anthropological aspects (Quedenfeldt, 1887; Lajard, 1891; Labouret, 1923), and it is only in the last part of the 20th century that serious attempts of describing their phonetics and acoustics have been made (Cowan, 1948; Classe, 1956; Busnel *et al.*, 1962; Busnel and Classe, 1976). More recently an international network of scientific researchers and local traditional authorities has been developed in a collaborative way (Meyer, 2004). This approach has emerged both from (a) the wish of some minority populations to revive, document, and transmit their threatened oral traditions and (b) the scientific assessment that these forms of communication provide significant information thanks to an alternative point of view of the phenomenon of language.

Diversity of Linguistic Production

Whistled forms of languages have been found in most of the main linguistic families. They rely mainly on a whistling technique and on a strategy of encoding, so every oral language may be whistled. Even some languages imported by waves of domination have been spontaneously adapted into a whistled equivalent, like Spanish Silbo of La Gomera, which evolved from a whistled form of a now extinct Berber language called Guanche.

Phonology and Phonetics

Linguists and acousticians noticed that two main ways of whistling a language have been developed. For tonal languages like Highland Mazateco, the pitch level of the main band of frequencies of the whistles characterizes the composition of the phonemes: in this case, whistles are focused on suprasegmental features and reproduce mainly the fundamental frequency of spoken

with a full academic status" (Louw, 1991: 19). In his retirement years Westphal left linguistics to join his second wife in her efforts to save penguins that had been victimized by oil spills.

Whistled Speech and Whistled Languages

J Meyer, Institut des Sciences de l'Homme, Lyon, France

B Gautheron, University of Paris III, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Several populations all over the world have naturally developed a whistled form of their local language in response to isolated conditions in their everyday life.

Whistled speech is a system of communication based on whistles modulated according to features in common with the spoken equivalent. Therefore, it is a vehicle for articulated language in the true sense of the word.

The fact that the information is quite unintelligible to untrained speakers long made whistled languages objects of mystery, even if their existence was reported since the treaty of the Tao in Asia (6th century B.C.) and since the 14th century in the island of La Gomera (Canary Islands). It is also the reason why so few researchers became interested in this alternative way of transmitting messages in a linguistic attitude.

The first scientific studies concerned mainly anthropological aspects (Quedenfeldt, 1887; Lajard, 1891; Labouret, 1923), and it is only in the last part of the 20th century that serious attempts of describing their phonetics and acoustics have been made (Cowan, 1948; Classe, 1956; Busnel *et al.*, 1962; Busnel and Classe, 1976). More recently an international network of scientific researchers and local traditional authorities has been developed in a collaborative way (Meyer, 2004). This approach has emerged both from (a) the wish of some minority populations to revive, document, and transmit their threatened oral traditions and (b) the scientific assessment that these forms of communication provide significant information thanks to an alternative point of view of the phenomenon of language.

Diversity of Linguistic Production

Whistled forms of languages have been found in most of the main linguistic families. They rely mainly on a whistling technique and on a strategy of encoding, so every oral language may be whistled. Even some languages imported by waves of domination have been spontaneously adapted into a whistled equivalent, like Spanish Silbo of La Gomera, which evolved from a whistled form of a now extinct Berber language called Guanche.

Phonology and Phonetics

Linguists and acousticians noticed that two main ways of whistling a language have been developed. For tonal languages like Highland Mazateco, the pitch level of the main band of frequencies of the whistles characterizes the composition of the phonemes: in this case, whistles are focused on suprasegmental features and reproduce mainly the fundamental frequency of spoken

languages. For nontonal languages like Spanish or Turkish, the pure frequency of whistles reproduces mainly segmental features of the language: the vowels are emitted at different pitch levels (the whistled series [i e a o u] results in descending pitches whereas modulations of these pitches convey the consonantal information. These consonantal modulations, when represented on sonograms, have a strong resemblance to the second formant of the spoken equivalent (Brusis, 1972; Busnel and Classe, 1976). This has been explained in terms of articulation. The transitions of the consonants are influenced by the pitch of the neighboring vowels, their whistled loci being reported to another set of frequencies (Leroy, 1970). This similarity, which has been partially studied in Spanish Silbo and in Turkish, is not systematic, is obvious in occlusive transitions, and tends to disappear in rapid whistles.

The constraints imposed by whistling techniques when articulated affect the phonetics and phonology. The whistled forms of languages have therefore been identified as abridgments of speech that encode essential parts of human languages. For example, in nontonal languages, there is a reduction of the number of vowels (to three or four main bands of frequencies representing the vowels) and consonants. In most tonal languages, the whistles reproduce tones and glides but not vowel qualities.

Lexicon

The vocabulary of whistled forms of languages reflects the basic knowledge of the vocal spoken language and has potentially the same richness. Whistlers culturally use a preferential set of words that correspond to their everyday activities. As a result, the dictionaries of common whistled words that have been gathered by researchers (Moles, 1970; Busnel and Classe, 1976) appear to be more restricted than the spoken dictionaries (there are approximately 2000 common words in La Gomera).

Whistles as a Tool for Linguists

Many linguists use whistles in their fieldwork as a tool to help them to sharpen the tonal description of their phonological modeling (even if the language has no naturally developed whistled system). The whistles might be used to focus on tonal rules (Cowan, 1948; Rialland, 1980) but also to look for any tonal aspect in a language described as nontonal (Caughley, 1976).

Geographical and Social Environments

Whistled languages have naturally developed in response to the necessity for humans to communicate in conditions of relative isolation (distance, night, noise) and specific activities (social information, shepherding, hunting or fishing, courtship, shamanism). Therefore, they are mostly related to places with mountains or dense forests. Southern China, Papua New Guinea, the Amazon forest, subsaharan Africa, Mexico, and Europe encompass most of these locations.

Native whistlers who have grown up in places where a whistled language was used daily do not remember when they began to control this aspect of the language. The learning process is the result of a phase when the person is immersed in a linguistic environment mixing whistled and spoken speech. Therefore, the whistled speech is locally simply seen as one of the multiple means of expressing the local language, like whispering, shouting, or singing.

Whistling Techniques

Many techniques have been described among the populations who whistle their language. The choice of a specific technique is first of all dependent on practical concerns. Bilabial and labiodental techniques are common for short and medium distance discussions (in a market, in the noise of a room, or for hunting); whereas the tongue retroflexed, one or two fingers introduced in the mouth, a blow concentrated at the junction between two fingers or the lower lip pulled while breathing in air are techniques used to reach high levels of power for long distance speaking. Each place has its favorite trend that depends on the most common use of the village and on the personal preferences of each whistler. Whistling with a leaf or a flute is often related to courtship or poetic expression (reported in the Kickapoo language in Mexico [Ritzenhaler and Peterson, 1954] and in the Hmong [Busnel *et al.*, 1989] and Akha [Meyer and Dentel, 2003] cultures in Asia). We may notice that the finger and the leaf can be seen as the first steps toward the use of an instrument (like jewharps, flutes, and drums to produce instrumentally played speech (Stern, 1957; Meyer, 2004).

Whistling techniques do not require the vibration of the vocal cords: they produce a shock effect of the compressed air stream inside the cavity of the mouth and/or of the hands. When the jaws are fixed by a finger, the size of the hole is stable. The air stream expelled makes vibrations at the edge of the mouth. The faster the air stream is expelled, the higher is the noise inside the cavities. If the hole (mouth) and the cavity (intra-oral volume) are well matched, the resonance is tuned, and the whistle is projected more loudly. The frequency of this bioacoustical phenomenon is modulated by the morphing of the

resonating cavity that can be, to a certain extent, related to the articulation of the equivalent spoken form.

Signal Characteristics and Audibility

The pitches of whistles are concentrated in a narrow bandwidth (1000 Hz to 3000 Hz) where the hearing in human beings is more sensitive and selective. The amplitude of whistled speech has reasonable limits in its dynamic range (less than 12 dB) whereas the range of spoken speech is more than 50 dB. In natural conditions the background noise is weak in high frequencies (except in windy weather) so the signal to noise ratio is better than 6 dB at 1 km and is enough to be clearly heard. Such properties explain the use of whistles in conditions of noise or long distance communication as they increase the resistance to background noise. Whistles are well carried in valleys, which form a natural guide. For example in La Gomera the signal remains understandable at 8 km (Busnel and Classe, 1976).

Intelligibility

One interesting and key aspect of whistled languages is their intelligibility. It is a principal functional parameter. Performance on recognition tests emphasizes the role of context (natural conditions of use) as an important aspect of the recognition task. Moreover, since the most common words are much more easily understood than others, there is a correlation between situational vocabulary and perception. The choice of words is targeted at phonetic clarity (in terms of whistled speech). At the same time, homophonies between words are avoided, at least in the context of the topic.

Some perceptual tests, made on nontonal forms of whistled languages, have shown that good whistlers can recognize phonemes of their language in audio signals of other languages.

An early study in neuroscience has shown that the brain areas of production (*Broca*) and perception (*Wernicke*) of language are activated in well trained listeners (former whistlers), but not in untrained ones, when they are presented with Silbo (Carreiras *et al.*, 2005).

Comparison with Language Perception of Persons Whose Hearing Is Impaired

Similar remarks concerning intelligibility can be made with people whose hearing is impaired. They have only some perception in low frequencies (corresponding to the prosodic patterns carried by the fundamental frequency and transposed in whistled speech) and use lip reading. To understand the meaning in a real time, their cognition task must test and verify many hypotheses in response to very poor phonetic cues (visual and auditory) in a strong context reinforced by many inputs such as: the topic (history, thema, and rhema), the situation (here and now), the relation with the talker (actual and past), and the feedback returned from the partner (well or not received).

Language Evolution and Whistled Language

Many aspects of whistled languages make them good candidates for the study of the evolution of languages. Their strong link with the ecological environment and their use in isolated conditions resulted in an adaptation to the performance of the hearing system and to the acoustical characteristics of both the producing system and the acoustical area. Their use in emergency situations or in contexts related to the local tradition has clear effects on lexical use. Moreover, a whistle is rich enough to transmit the essential aspect of the languages of the world without requiring the intervention of the vocal cords. The transfer of the whistling technique from one local language to another makes this practice resistant to language domination provided that the traditional way of life is maintained. In some locations, the whistles and some musical instruments are used both for transmitting messages of linguistic attitude and for traditional music. The careful analysis of the phonetic degradation of whistled and instrumentally played languages in the places where they are endangered is in progress (Meyer, 2004).

Biolinguistic Diversity Endangered

Whistled languages are a reliable human indicator of the vitality of the traditional way of life of the cultures that developed them. The gradual disappearance of activities like shepherding and the aging of rural populations are the main reasons for the extinction of an articulated whistled form in France (Aas). Most whistled languages are almost extinct due to the combined effects of the depreciation of the local culture and of the rural exodus. The gradual disappearance of whistled speech and its scientific interest underline the fact that linguistic biodiversity and cultural and scientific richness are both shrinking.

In some particular places, this tendency has already been reversed. For example, in the Canary Islands, the process of revitalization carried out by elders on a voluntary basis has recently been supported by local

education. In Mexico, some indigenous local councils have made the oral tradition one of their priorities, including local dances, traditional medicine, and whistled speech in their language.

Whitney, William Dwight (1827–1894)

E F K Koerner, Zentrum für Allgemeine Sprachwissenschaft, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Whitney was born in Northampton, Massachusetts, on February 9, 1827, and died in New Haven, Connecticut, on June 7, 1894. He is best known as a general linguist and Sanskrit scholar. He was the brother of the geologist Josiah Dwight Whitney (1819–1996), after whom the highest mountain in the United States (excluding Alaska), Mount Whitney, California, is named, and William Whitney's early interests lay in the natural sciences, notably ornithology and geology. It is therefore not surprising that he introduced into linguistic theory and practice notions derived from geology, which he had absorbed from Charles Lyell's voluminous *Principles of geology* (1830–1833) and other scientific writings, notably the concept of 'uniformitarianism.' His education included a period at Williams College, New Haven, Connecticut (1842–1845), after which he devoted himself for three years to bird- and plant-collecting. Part of his collections subsequently went into the Peabody Museum of New Haven.

However, books on comparative philology, especially Sanskrit, which his elder brother had brought back from Europe, attracted his interest, and after another stint with the U. S. Geological Survey, he enrolled at Yale College in 1849. A year later, he left for Germany, studying at the University of Berlin with Franz Bopp, Carl-Richard Lepsius, and Albrecht Weber, and at Tübingen with Rudolf von Roth for almost three years (late 1850–July 1853). Whitney

education. In Mexico, some indigenous local councils have made the oral tradition one of their priorities, including local dances, traditional medicine, and whistled speech in their language.

Whitney, William Dwight (1827–1894)

E F K Koerner, Zentrum für Allgemeine Sprachwissenschaft, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Whitney was born in Northampton, Massachusetts, on February 9, 1827, and died in New Haven, Connecticut, on June 7, 1894. He is best known as a general linguist and Sanskrit scholar. He was the brother of the geologist Josiah Dwight Whitney (1819–1996), after whom the highest mountain in the United States (excluding Alaska), Mount Whitney, California, is named, and William Whitney's early interests lay in the natural sciences, notably ornithology and geology. It is therefore not surprising that he introduced into linguistic theory and practice notions derived from geology, which he had absorbed from Charles Lyell's voluminous *Principles of geology* (1830–1833) and other scientific writings, notably the concept of 'uniformitarianism.' His education included a period at Williams College, New Haven, Connecticut (1842–1845), after which he devoted himself for three years to bird- and plant-collecting. Part of his collections subsequently went into the Peabody Museum of New Haven.

However, books on comparative philology, especially Sanskrit, which his elder brother had brought back from Europe, attracted his interest, and after another stint with the U. S. Geological Survey, he enrolled at Yale College in 1849. A year later, he left for Germany, studying at the University of Berlin with Franz Bopp, Carl-Richard Lepsius, and Albrecht Weber, and at Tübingen with Rudolf von Roth for almost three years (late 1850–July 1853). Whitney

worked in particular with Weber and Roth on Sanskrit texts, which culminated in his editions of several important Atharva–Veda texts between 1860 and the end of his life.

On his return to America he was appointed Professor of Sanskrit at Yale University (1854), and when he was approached by Harvard in 1869, Yale also offered him the professorship of comparative philology. Whitney remained at New Haven for the rest of his life except for several trips to Europe, in particular Germany, where he completed his Sanskrit grammar (1879). He was the most important figure in 19th-century American linguistics, dominating the field for almost four decades, both as a scholar and organizationally, for example, as librarian (1855–1873), corresponding secretary (1857–1884), and finally president (1884–1890) of the American Oriental Society. His influence on academic appointments throughout the United States appears to have been enormous; his service as editor-in-chief of the *Century dictionary* (New York, 1889–1891) was another means of leaving his imprint on American science. He received many honors during his career, beginning with Doctor of Philosophy from the University of Breslau in 1861, and followed by honorary doctorates from his alma mater (1868), College of William & Mary (1869), St Andrews, Scotland (1874), Harvard (1876), Columbia (1887), and Edinburgh (1889), memberships in many scholarly societies and academies, and other distinctions such as the Bopp Prize (1871) and Foreign Knight of the Prussian order 'pour le mérite' for arts and sciences. Whitney's chief claim to distinction came from his work in Indic philology, both text editions and the *Sanskrit grammar* of 1879, and from his two books on general linguistics (1867, 1875); his ongoing polemic with Max Müller of Oxford may have detracted from his importance as a sound methodologist of linguistic science, but as the testimonies of the greats of nineteenth-century scholarship in the field, delivered at the 1894 Whitney Memorial Meeting, show (Lanman, 1897), he was regarded by them as a significant influence on their work (Jakobson, 1971). The importance of some of his pronouncements on matters of general linguistic theory for Saussure, notably his emphasis on the social nature of language and the conventional and arbitrary character of the linguistic sign, has become generally recognized (cf. Koerner, 1973: 74–100, for details).

Whole Word Morphology

R Singh, University of Montreal, Montreal, Canada

© 2006 Elsevier Ltd. All rights reserved.

Whole Word Morphology (sometimes called Seamless Morphology) is a truly word-based theory of morphology – truly word-based because it does not allow morphological operations on units smaller than the word. It is an attempt to solve the problems entailed by the view of morphology as a combinatorics of morphs or morphemes. The main problems with that view are that (1) it cannot in principle state some generalizations that need to be stated or can state them only by undercutting itself in irreparable ways, and (2) there seems to be no principled way to characterize the pieces such a view wants to restrict itself to and construct a combinatorics of (cf. the difficulties associated with the segmentation of non-affixal morphology and the inability of the advocates of such a view to stop their procedures from producing units such as semiaffixes, interfixes, affixoids, quasimorphs, morphological 'helpers,' 'shapers,' and even Firthian phonesthemes).

Whole Word Morphology was first outlined in Ford and Singh (1991). A fuller, monographic sketch of it appeared in Ford *et al.* (1997). Since then, various aspects of it have been elaborated on, and it has been tested against the empirical facts of several languages (e.g., Singh, 1996, 2001; Singh and Agnihotri, 1997; Singh and Dasgupta, 1999; Singh and Ford, 2000; Becker, 2000; Neuvel, 2003; Singh and Neuvel, 2003; Singh and Starosta, 2003).

What Whole Word Morphology says is summarized next. The first paragraph is the heart of the matter; the second paragraph is an explicatory postscript.

All that needs to be said about word structure in any language (of any type whatsoever) can and must be said by instantiations of the schema in (S1). These instantiations are referred to as Word Formation Strategies (WFSs) because, as generalizations drawn from known particular facts, they can be activated in the production and understanding of new words. WFSs must be formulated as generally as possible, but – and this is crucial – only as generally as the facts of the matter permit.

S1. $/ X /_a \leftrightarrow / X' /_b$

where:

1. $/ X /_a$ and $/ X' /_b$ are words and X and X′ are abbreviations of the forms of classes of words belonging to categories a and b (with which specific words belonging to the right category can be unified or on to which they can be mapped).
2. ′ represents (all the) form-related differences between / X / and / X′ / that fall outside of automatic phonology.
3. a and b are categories that may be represented as feature bundles.
4. The ↔ represents a bidirectional implication (if X, then X′, and if X′, then X).
5. The interpretation of $/ X /_a$ is a semantic function of $/ X' /_b$ and vice versa.
6. ′ can be null iff $a \neq b$.

It should be obvious that according to Seamless Morphology

1. Morphological complexity is a matter of the analyzability (≠ segmentability) of a word into a variable and a constant component with respect to a WFS.
2. 'Morphophonology' (or its contemporary *avatar* 'lexical phonology') is an integral part of morphology (cf. point 2 in the first paragraph).
3. Both intralinguistic (inflection vs. derivation, affixation vs. compounding, etc.) and interlinguistic (flectional, isolating, etc.) morphological diversity can be derived from S1 without affecting it in any fundamental way.
4. S1 offers a unified account of what have sometimes been seen as different types of morphologies and encapsulates the rejection of multipartite analysis of words into 'roots,' 'affixes,' 'stems,' and so on, entities that are hard to define and harder to tell apart.
5. Neither the strategies nor their 'outputs' have any syntactic constituency relationships marked in them in any fashion whatsoever. These strategies license the words a speaker has or may come up with.

Whole Word Morphology, to summarize, sees morphology not as a combinatorics of morphs or morphemes but as a system of generalized and abstract bidirectional correspondences among patterns instantiated by sets of whole words that exploit the same contrast. Although this contrast can be just formal (i.e., form-related) for some, for example, Ford and Singh, who take a dissociative view of morphology (cf. Corbin, 1987) and postulate the existence of rules of interpretation associated with WFSs, some advocates of Seamless Morphology (Neuvel and Starosta, for example) subscribe to what Corbin calls the 'associative' view and require it (i.e., the contrast in question) to be **both** formal and semantic. These correspondences of patterns are exploited by speakers to

create new words, reconstruct words they have forgotten, and interpret morphologically complex words they have not heard before.

Whorf, Benjamin Lee (1897–1941)

T C Christy, University of North Alabama, Florence, AL, USA

© 2006 Elsevier Ltd. All rights reserved.

A self-taught linguist, who also studied American Indian linguistics under Edward Sapir at Yale, Benjamin Lee Whorf is best known for his work in developing the 'Sapir-Whorf' or 'linguistic relativity hypothesis,' the central claim of which – that the structures of language, in addition to providing a vehicle for the expression of thought, also shape thought by casting it in the mold of language-specific patternings – echoes views advanced in the early 19th century by Wilhelm von Humboldt in his writings on linguistic diversity. In Whorf's words, "... the world is presented in a kaleidoscopic flux of impressions which has to be organized by our minds – and this means largely by the linguistic systems in our minds" (Carroll, 1956: 213). Whorf's study of American Indian languages – for example Uto-Aztecan (Aztec and, in particular, Hopi) and Mayan (Maya) – convinced him that the grammatical categories of languages structure both perception and conceptualization. He developed this hypothesis principally in his papers "Grammatical categories," "Some verbal categories of Hopi," and "The relation of habitual thought and behavior to language" (1939), all of which are reprinted, along with other of Whorf's published and unpublished writings, by John Carroll (1956), who, in his introduction to this volume, provided much useful biographical information. The linguistic relativity hypothesis is notoriously difficult to corroborate or refute, with empirical evidence, involving, as it does, the calibration of linguistic with cultural and cognitive considerations. The limited evidence produced to date – for example, cross-linguistic surveys of color terminology (Berlin and Kay, 1969) – has both undermined the strong version of the hypothesis, according to which language determines and limits, as opposed to influencing, the architecture of cognition, and called attention to the influence of other factors. While the focus of the linguistic relativity hypothesis is squarely on the relation of language to thought, clearly biological constraints on perception, as well as cultural influences, are also involved. The difficulties attending ascertaining where one influence begins and the other ends have contributed to the still largely indeterminate status of the linguistic relativity hypothesis. Moreover, the sheer fact that translation from one language to another is possible diminishes the likelihood that languages differ by entire categories of thought. Last, linguistic universals, by definition, also put an upward limit on the reach of linguistic relativity.

create new words, reconstruct words they have forgotten, and interpret morphologically complex words they have not heard before.

Wierzbicka, Anna (b. 1938)

M Miskovic-Lukovic, Institut für Fremdsprachenphilologien, Oldenburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Anna Wierzbicka, the founder and leading exponent of natural semantic metalanguage (NSM) theory, is internationally known for her work in semantics, syntax, pragmatics, and cross-cultural linguistics. Her theory combines a radically universalist approach, that human concepts are innate, with a relativist approach, that ordinary languages have different semantic systems representing culture-specific configurations of universal semantic primitives.

Wierzbicka was born in 1938 in Warsaw, Poland. Early in her childhood she evinced a keen interest in language, playing word games with her father and writing poetry. A Polish Catholic, who lived in her homeland until 1972, she had little sympathy for Communist ideology.

Wierzbicka's academic career began at the University of Warsaw. After receiving a Ph.D. from the Polish Academy of Sciences, she continued postdoctoral studies in Moscow in 1965. In 1966, she spent a year studying and researching at MIT. In 1972, she settled in Canberra, Australia. Wierzbicka is a professor of linguistics at the Australian National University. She is a Fellow of the Australian Academy of the Humanities and Australian Academy of Social Sciences and has also been awarded the Humboldt Research Prize for Foreign Scholars in Humanities.

Her principal publications include *Semantic primitives* (1972), *Lingua mentalis: the semantics of natural language* (1980a), *The case for surface case* (1980b), *Lexicography and conceptual analysis* (1985), *English speech act verbs: a semantic dictionary* (1987), *The semantics of grammar* (1988), *Cross-cultural pragmatics: the semantics of human interaction* (1991), *Semantics, culture and cognition: universal human concepts in culture-specific configurations* (1992), *Semantics: primes and universals* (1996), *Understanding cultures through their key words: English, Russian, Polish, German, Japanese* (1997), *Emotions across languages and cultures: diversity and universals* (1999), and *What did Jesus mean? Explaining the Sermon on the Mount and the parables in simple and universal human concepts* (2001).

Wierzbicka's scholarship is characterized by the search for 'semantic primes,' a small core of irreducible universal meanings, which can be found as words, bound morphemes, or phrasemes in all languages. The theory rests on the following premises: semantic analysis must be conducted in natural language; complex meanings can be stated in terms of simpler ones (reductive paraphrase); the NSMs of all languages are isomorphic. The NSM approach to meaning is intensional – semantic primes are conceptual but they are not abstract, they correspond to word meanings in ordinary language. Over the period of 30 years of extensive empirical, cross-linguistic investigations, Wierzbicka and her colleagues have collected a set of about 60 lexical universals (e.g., A LONG TIME, DO, GOOD, PEOPLE, etc.). This 'mini-lexicon' of semantic primes and the manner of their combination constitute a metalanguage that is supposed to have the same expressive power as any ordinary language.

Anna Wierzbicka, the founder and leading exponent of natural semantic metalanguage (NSM) theory, is internationally known for her work in semantics, syntax, pragmatics, and cross-cultural linguistics. Her theory combines a radically universalist approach, that human concepts are innate, with a relativist approach, that ordinary languages have different semantic systems representing culture-specific configurations of universal semantic primitives.

Wierzbicka was born in 1938 in Warsaw, Poland. Early in her childhood she evinced a keen interest in language, playing word games with her father and writing poetry. A Polish Catholic, who lived in her homeland until 1972, she had little sympathy for Communist ideology.

Wierzbicka's academic career began at the University of Warsaw. After receiving a Ph.D. from the Polish Academy of Sciences, she continued postdoctoral studies in Moscow in 1965. In 1966, she spent a year studying and researching at MIT. In 1972, she settled in Canberra, Australia. Wierzbicka is a professor of linguistics at the Australian National University. She is a Fellow of the Australian Academy of the Humanities and Australian Academy of Social Sciences and has also been awarded the Humboldt Research Prize for Foreign Scholars in Humanities.

Her principal publications include *Semantic primitives* (1972), *Lingua mentalis: the semantics of natural language* (1980a), *The case for surface case* (1980b), *Lexicography and conceptual analysis* (1985), *English speech act verbs: a semantic dictionary* (1987), *The semantics of grammar* (1988), *Cross-cultural pragmatics: the semantics of human interaction* (1991), *Semantics, culture and cognition: universal human concepts in culture-specific configurations* (1992), *Semantics: primes and universals* (1996), *Understanding cultures through their key words: English, Russian, Polish, German, Japanese* (1997), *Emotions across languages and cultures: diversity and universals* (1999), and *What did Jesus mean? Explaining the Sermon on the Mount and the parables in simple and universal human concepts* (2001).

Wierzbicka's scholarship is characterized by the search for 'semantic primes,' a small core of irreducible universal meanings, which can be found as words, bound morphemes, or phrasemes in all languages. The theory rests on the following premises: semantic analysis must be conducted in natural language; complex meanings can be stated in terms of simpler ones (reductive paraphrase); the NSMs of all languages are isomorphic. The NSM approach to meaning is intensional – semantic primes are conceptual but they are not abstract, they correspond to word meanings in ordinary language. Over the period of 30 years of extensive empirical, cross-linguistic investigations, Wierzbicka and her colleagues have collected a set of about 60 lexical universals (e.g., A LONG TIME, DO, GOOD, PEOPLE, etc.). This 'mini-lexicon' of semantic primes and the manner of their combination constitute a metalanguage that is supposed to have the same expressive power as any ordinary language.

The metalanguage has a wide range of applications, such as intercultural communication, language acquisition and teaching, language typology, legal semantics, and lexicography. Additionally, it serves as a basis for an emergent theory of cultural scripts, considered as shared interpretive background, and used for the description of the 'verbal culture' of any society.

Wiesemann, Ursula (b. 1932)

U Seibert, University of Giessen, Giessen, Germany

© 2006 Elsevier Ltd. All rights reserved.

Ursula Wiesemann was born in Berlin in 1932. After attending a summer course in linguistics at the University of Oklahoma, she became a member of the Summer Institute of Linguistics (SIL) in 1956. For the next 20 years, she worked among the Kaingáng, a small ethnic group in Brazil, studying their language, developing literacy material, training teachers, and translating the New Testament into Kaingáng. During this time, she continued studying linguistics, ethnology, English, and phonetics at the University of Cologne, where she received her Ph.D. in 1966.

From Brazil, she moved to Africa, where she worked as a professor in Cameroon (1980–1986) and Benin (1988–1994) and helped train mother-tongue linguists and translators in several other countries.

Wiesemann initiated and taught a number of linguistics and applied linguistics courses, including 'Discover Your Language – A Course in Applied Linguistics,' Tone Analysis, Phonology, Orthography Development, Discourse Analysis, and Foreign Language Acquisition. She has taught these courses both at universities and during workshops in many countries, including Brazil, Germany, Benin, Cameroon, Congo, Togo, Senegal, and Mocambique.

In 1962, 1964–1966, 1969, 1971, and from 1994 until her retirement, she directed the *Seminar für Sprachmethodik*, a yearly summer course in applied linguistics run by the German branch of SIL in Burbach-Holzhausen. She directed a similar course in Brazil in 1976–1978.

In the past few years she has returned to Brazil in order to help develop the Kaingáng language, her first love.

Ursula Wiesemann has inspired and taught whole generations of linguistics students, mother-tongue linguists, translators, and literacy teachers. In addition, she has freely offered her knowledge and expertise as a consultant to numerous literacy projects. She has published numerous books and articles in German, English, French, and Portuguese. The topics of her publications include phonology, orthography development, morphology, syntax, discourse analysis, translation theory, and foreign language acquisition.

But even though she is such a distinguished and productive scholar, she has remained a very humble person who lives her Christian faith in a practical manner.

The metalanguage has a wide range of applications, such as intercultural communication, language acquisition and teaching, language typology, legal semantics, and lexicography. Additionally, it serves as a basis for an emergent theory of cultural scripts, considered as shared interpretive background, and used for the description of the 'verbal culture' of any society.

Wilkins, John (1614–1672)

J L Subbiondo

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 9, pp. 4983–4984, © 1994, Elsevier Ltd.

John Wilkins's scholarly interests reflected the panorama of 17th-century British thought: in addition to his work in linguistics, he distinguished himself in education, lexicography, oratory, science, theology, and taxonomy. His principal contribution to the intellectual life of 17th-century Britain was his role as principal founder of the Royal Society, and his contribution to the history of linguistics was his leadership in developing the most comprehensive universal or philosophical language to date (*see* **Universal Language Schemes in the 17th Century**).

Born in 1614, Wilkins was educated at Magdalen Hall, Oxford, and upon graduation, he was appointed tutor there in 1634. He was ordained in 1637 and appointed Vicar of Fawsley, and later served as private chaplain first to Lord Berkeley and then to Prince Elector Palatine Charles Louis. In 1648, he was appointed Warden of Wadham College, Oxford, and there received his Doctorate of Divinity. He was appointed Master of Trinity College, Cambridge in 1659; Bishop of Chester in 1668; and, after his resignation, he held a variety of clerical positions in London until his death in 1672.

A significant promoter of the scientific activities of his day, he led the philosophical or universal language movement which attempted to invent an artificial language to remedy the deficiencies of natural languages. There was considerable concern on the part of 17th-century scientists that the imprecision of natural languages threatened the advancement and preservation of science. In his *Mercury* (1641), Wilkins advanced a system of cryptology in which he designed a secret language. Expanding the theoretical construct of that design, Wilkins developed the most extensive philosophical language ever devised in his monumental *Essay towards a Real Character, and a Philosophical Language* (1668). In the initial phase of his project, Wilkins worked closely with George Dalgarno (*see* **Dalgarno, George (ca. 1619–1687)**), but soon after, he decided not to collaborate with Dalgarno because their goals grew incompatible.

Wilkins's first task in the development of his philosophical language was to compile detailed charts reflecting the knowledge of the universe shared by his colleagues in the Royal Society. He then designed a graphemic system, a 'real character,' and a phonetic system capable of signifying each element in his charts. (For his phonetics *see* **Phonetics: Precursors to Modern Approaches** and **Phonetic Transcription: History**). The symbols of the elements were formed into words and the words were placed in logical order into sentences. He arranged the elements according to

John Wilkins's scholarly interests reflected the panorama of 17th-century British thought: in addition to his work in linguistics, he distinguished himself in education, lexicography, oratory, science, theology, and taxonomy. His principal contribution to the intellectual life of 17th-century Britain was his role as principal founder of the Royal Society, and his contribution to the history of linguistics was his leadership in developing the most comprehensive universal or philosophical language to date (*see* **Universal Language Schemes in the 17th Century**).

Born in 1614, Wilkins was educated at Magdalen Hall, Oxford, and upon graduation, he was appointed tutor there in 1634. He was ordained in 1637 and appointed Vicar of Fawsley, and later served as private chaplain first to Lord Berkeley and then to Prince Elector Palatine Charles Louis. In 1648, he was appointed Warden of Wadham College, Oxford, and there received his Doctorate of Divinity. He was appointed Master of Trinity College, Cambridge in 1659; Bishop of Chester in 1668; and, after his resignation, he held a variety of clerical positions in London until his death in 1672.

A significant promoter of the scientific activities of his day, he led the philosophical or universal language movement which attempted to invent an artificial language to remedy the deficiencies of natural languages. There was considerable concern on the part of 17th-century scientists that the imprecision of natural languages threatened the advancement and preservation of science. In his *Mercury* (1641), Wilkins advanced a system of cryptology in which he designed a secret language. Expanding the theoretical construct of that design, Wilkins developed the most extensive philosophical language ever devised in his monumental *Essay towards a Real Character, and a Philosophical Language* (1668). In the initial phase of his project, Wilkins worked closely with George Dalgarno (*see* **Dalgarno, George (ca. 1619–1687)**), but soon after, he decided not to collaborate with Dalgarno because their goals grew incompatible.

Wilkins's first task in the development of his philosophical language was to compile detailed charts reflecting the knowledge of the universe shared by his colleagues in the Royal Society. He then designed a graphemic system, a 'real character,' and a phonetic system capable of signifying each element in his charts. (For his phonetics *see* **Phonetics: Precursors to Modern Approaches** and **Phonetic Transcription: History**). The symbols of the elements were formed into words and the words were placed in logical order into sentences. He arranged the elements according to

meaning – an approach later adopted by Peter Roget who credited Wilkins in the preface of his famous thesaurus. Wilkins provided a dictionary which served as an alphabetical index for locating elements in his charts. Dolezal (1985) has convincingly pointed out that this dictionary merits recognition in the history of lexicography.

In late 20th-century scholarship, Wilkins draws growing attention as a significant thinker of his time and also as a substantive pioneer in semiotic theory.

Wilks, Yorick (b. 1939)

I Mani, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Yorick Wilks obtained his Ph.D. at Cambridge University in 1968, where he developed the initial ideas of what came to be called 'preference semantics.' This is a computational theory of semantics focused on semantic disambiguation. In brief, given a set of possible meanings for a sentence, including nonliteral ones, the computed interpretation is the one that leads to the fewest possible selectional preferences being violated. His early contributions to computational semantics also included modeling of beliefs and point-of-view of agents in human–computer interaction. These fundamental approaches were complemented by a deep and abiding interest in questions in the philosophy of mind and the relation of linguistics to artificial intelligence.

Wilks's interest in artificial intelligence took him to the Artificial Intelligence Laboratory at Stanford, where he worked from 1970 to 1974. Following a stint in Edinburgh, he joined the University of Essex, working there from 1976 to 1985, a period that saw a great maturing of the field of natural language processing. From Essex, he went on to New Mexico State University, where he became professor of computer science and director of the Computing Research Laboratory, staying there until 1998, when he joined the University of Sheffield, where he is professor of computer science and founding director of the Institute for Language, Speech, and Hearing. At these institutions, Wilks was able to create world-class teams of researchers and top-notch (and well-endowed) centers for research in natural language processing.

During the course of a career that has included 11 books and hundreds of papers, Wilks and his research teams have made basic contributions to a number of key areas in natural language processing. Preference semantics provided a foundation for his own research in processing metaphorical language and on disambiguating word senses, in turn influencing other research in these areas. Whereas his work in the early 1970s, like that of other influential work of the time, was heavily knowledge based, with a commitment to decomposition of meaning into semantic primitives, his subsequent research in several areas combined human-engineered rules with linguistic and statistical information gleaned from text corpora. At New Mexico, he led successful efforts to mine machine-readable dictionaries for knowledge that could then be tuned with statistical information from text corpora.

With the surge of research in information extraction in the 1990s, his group at New Mexico and then at Sheffield developed a variety of empirically driven approaches to information extraction, as well as the Sheffield GATE architecture for natural language processing. Other research in which he has invested substantial effort includes parsing and its evaluation, machine translation, the modeling of dialogue and conversational agents, and the relationship between language and vision.

Wilks has always been very visible in the field, serving on numerous program committees and the editorial boards of many journals. He has also been a lively and opinionated commentator on the evolution

meaning – an approach later adopted by Peter Roget who credited Wilkins in the preface of his famous thesaurus. Wilkins provided a dictionary which served as an alphabetical index for locating elements in his charts. Dolezal (1985) has convincingly pointed out that this dictionary merits recognition in the history of lexicography.

In late 20th-century scholarship, Wilkins draws growing attention as a significant thinker of his time and also as a substantive pioneer in semiotic theory.

William of Conches (ca. 1080–1154)

L Kaczmarek, Borgholzhausen, Germany

© 2006 Elsevier Ltd. All rights reserved.

Most of his biographers agree that William of Conches was born ca. 1085–1090 in Conches-en-Ouche near Évreux, France, "in a country of mutton-heads under the dense sky of Normandy," as he writes in a Juvenalian mood in his *Dragmaticon* VI, 1 (1997: 179).

A pupil of Bernard of Chartres and philosophically a platonist who tried to reconcile Christian faith and ancient philosophy, William was interested in topics like cosmology and medicine, but never forgot to stress grammar's important position in the circle of learning. John of Salisbury lists him as his revered teacher in his *Metalogicon*. William glossed over Plato, Macrobius, and Boethius. The gloss on Juvenal's *Satires* is no longer considered his work.

William of St. Thierry's attempt to denounce him in a letter to Bernard of Clairvaux as a nobody without any authority, and even a heretic, caused William of Conches, in the long run, to revise his *Philosophia* under the title of *Dragmaticon*, purporting it to be written by a 'nameless philosopher,' at some time between 1144 and 1151, when he tutored Henry, the son of the Duke of Normandy, Geoffrey Plantagenet (d. 1151), and future King of England.

One of William's main concerns in semantic theory was to find out and describe the appropriate *causae inventionis* (reasons for invention) for words and their classes he missed in Priscian (see his *Philosophia*, 1980: III, Section 59). A master of strong argument, he called those who confuse language and reality "sensual and beastly grammarians" (XVII, Section 16).

There is a series of redactions (*correptiones*) of his *Glosae super Priscianum* (see Fredborg, 1973, 1981). William, who draws on the late 11th-century *Glosulae*-tradition (see Rosier, 1993 and Rosier-Catach, 2005), worked on the text for the first time ca. 1120, probably in Chartres, went over it again more than 20 years later somewhere else, and later again, as there is a fragment of a different third version. Extracts from the text are printed in Jeauneau (1960: 243–347), in Fredborg (1973, 1981), and in Rosier (1993: 131–144). A critical edition of the *Glosae* is in preparation by I. Caiazzo as part of William's *Opera omnia*. The *Glosae* (1st redaction) influenced Peter Helias and are echoed in the anonymous gloss *Promisimus* about 50 years later. William of Conches was reported still alive in 1154.

William of Conches (ca. 1080–1154)

L Kaczmarek, Borgholzhausen, Germany

© 2006 Elsevier Ltd. All rights reserved.

Most of his biographers agree that William of Conches was born ca. 1085–1090 in Conches-en-Ouche near Évreux, France, "in a country of mutton-heads under the dense sky of Normandy," as he writes in a Juvenalian mood in his *Dragmaticon* VI, 1 (1997: 179).

A pupil of Bernard of Chartres and philosophically a platonist who tried to reconcile Christian faith and ancient philosophy, William was interested in topics like cosmology and medicine, but never forgot to stress grammar's important position in the circle of learning. John of Salisbury lists him as his revered teacher in his *Metalogicon*. William glossed over Plato, Macrobius, and Boethius. The gloss on Juvenal's *Satires* is no longer considered his work.

William of St. Thierry's attempt to denounce him in a letter to Bernard of Clairvaux as a nobody without any authority, and even a heretic, caused William of Conches, in the long run, to revise his *Philosophia* under the title of *Dragmaticon*, purporting it to be written by a 'nameless philosopher,' at some time between 1144 and 1151, when he tutored Henry, the son of the Duke of Normandy, Geoffrey Plantagenet (d. 1151), and future King of England.

One of William's main concerns in semantic theory was to find out and describe the appropriate *causae inventionis* (reasons for invention) for words and their classes he missed in Priscian (see his *Philosophia*, 1980: III, Section 59). A master of strong argument, he called those who confuse language and reality "sensual and beastly grammarians" (XVII, Section 16).

There is a series of redactions (*correptiones*) of his *Glosae super Priscianum* (see Fredborg, 1973, 1981). William, who draws on the late 11th-century *Glosulae*-tradition (see Rosier, 1993 and Rosier-Catach, 2005), worked on the text for the first time ca. 1120, probably in Chartres, went over it again more than 20 years later somewhere else, and later again, as there is a fragment of a different third version. Extracts from the text are printed in Jeauneau (1960: 243–347), in Fredborg (1973, 1981), and in Rosier (1993: 131–144). A critical edition of the *Glosae* is in preparation by I. Caiazzo as part of William's *Opera omnia*. The *Glosae* (1st redaction) influenced Peter Helias and are echoed in the anonymous gloss *Promisimus* about 50 years later. William of Conches was reported still alive in 1154.

Introduction

Chance genetic events sometimes give rise through development to interesting cognitive-level outcomes. William's Syndrome (henceforth WS), a neurodevelopmental disorder, is one such case. At first blush, individuals with WS seem to have intact language alongside IQs in the 50–60s range. Does this mean that language has developed independently of intelligence and that the existence of WS supports Nativist views concerning the innate pre-specification of language? In this entry, we note that, despite the understandable initial excitement about the ostensibly intact linguistic capacities of this clinical group, in fact their language development follows an atypical pathway from infancy through to adulthood. Moreover, the Nativist literature frequently misrepresents the empirical findings about WS language by treating *relative* strengths as *absolute* strengths, i.e., intactness of function. Here we present evidence to demonstrate how WS language processes actually display subtle impairments (Karmiloff-Smith, Brown *et al.*, 2003) and cannot serve to segregate the WS cognitive system into parts that develop normally and independently of parts that develop atypically. It should be recalled that such adult patients had normal development prior to their brain insult. In the case of developmental disorders, by contrast, subtle initial impairments may affect numerous parts of the brain as it develops. One cannot simply assume that deficits in the phenotypic outcome are the same as those apparent in the infant start state (Paterson *et al.*, 1999). Indeed, even in the normal case, ontogenetic development plays an important role over time. Infants do not start life with the same brain structure as adults. Ontogenesis progressively gives rise to adult specialization and localization of function. Thus, higher-level specializations such as morphology, syntax, the lexicon, and pragmatics are likely to be the emergent product of development rather than its starting state (Karmiloff-Smith, 1992).

William's Syndrome

William's Syndrome occurs in approximately 1 in 20 000 live births and is caused by the deletion of some 26 genes on one copy of chromosome 7 (Donnai and Karmiloff-Smith, 2000). Clinical features include several physical abnormalities that are accompanied by mental retardation and a specific personality profile. The interest in WS to neuroscientists, linguists, and psycholinguists stems from the syndrome's uneven profile of cognitive abilities, with spatial and numerical cognition seriously impaired, while language, social interaction, and face processing seem surprisingly proficient for a clinical population with a mean IQ of 56 (Bellugi *et al.*, 1994; Udwin and Yule, 1991). Research by Bellugi and her collaborators first drew attention to the potential theoretical interest to psycholinguistics of these seeming dissociations in the WS phenotype (Bellugi *et al.*, 1988). Surprising proficiency with language was shown to coexist with serious problems on nonverbal tasks, in particular those calling on visual-spatial processing. However, as researchers subsequently examined in more depth the linguistic profile of individuals with WS, it became apparent that the static notions of 'intactness' and of 'selective dissociations' needed to be replaced with a developmental notion of 'atypically developing trajectories' over time (Karmiloff-Smith, 1998; Karmiloff-Smith, Scerif *et al.*, 2003; Karmiloff-Smith, 2004). We focus here on how the linguistic trajectory in WS develops, arising initially from the unusual communicative and cognitive

Introduction

Chance genetic events sometimes give rise through development to interesting cognitive-level outcomes. William's Syndrome (henceforth WS), a neurodevelopmental disorder, is one such case. At first blush, individuals with WS seem to have intact language alongside IQs in the 50–60s range. Does this mean that language has developed independently of intelligence and that the existence of WS supports Nativist views concerning the innate pre-specification of language? In this entry, we note that, despite the understandable initial excitement about the ostensibly intact linguistic capacities of this clinical group, in fact their language development follows an atypical pathway from infancy through to adulthood. Moreover, the Nativist literature frequently misrepresents the empirical findings about WS language by treating *relative* strengths as *absolute* strengths, i.e., intactness of function. Here we present evidence to demonstrate how WS language processes actually display subtle impairments (Karmiloff-Smith, Brown *et al.*, 2003) and cannot serve to segregate the WS cognitive system into parts that develop normally and independently of parts that develop atypically. It should be recalled that such adult patients had normal development prior to their brain insult. In the case of developmental disorders, by contrast, subtle initial impairments may affect numerous parts of the brain as it develops. One cannot simply assume that deficits in the phenotypic outcome are the same as those apparent in the infant start state (Paterson *et al.*, 1999). Indeed, even in the normal case, ontogenetic development plays an important role over time. Infants do not start life with the same brain structure as adults. Ontogenesis progressively gives rise to adult specialization and localization of function. Thus, higher-level specializations such as morphology, syntax, the lexicon, and pragmatics are likely to be the emergent product of development rather than its starting state (Karmiloff-Smith, 1992).

William's Syndrome

William's Syndrome occurs in approximately 1 in 20 000 live births and is caused by the deletion of some 26 genes on one copy of chromosome 7 (Donnai and Karmiloff-Smith, 2000). Clinical features include several physical abnormalities that are accompanied by mental retardation and a specific personality profile. The interest in WS to neuroscientists, linguists, and psycholinguists stems from the syndrome's uneven profile of cognitive abilities, with spatial and numerical cognition seriously impaired, while language, social interaction, and face processing seem surprisingly proficient for a clinical population with a mean IQ of 56 (Bellugi *et al.*, 1994; Udwin and Yule, 1991). Research by Bellugi and her collaborators first drew attention to the potential theoretical interest to psycholinguistics of these seeming dissociations in the WS phenotype (Bellugi *et al.*, 1988). Surprising proficiency with language was shown to coexist with serious problems on nonverbal tasks, in particular those calling on visual-spatial processing. However, as researchers subsequently examined in more depth the linguistic profile of individuals with WS, it became apparent that the static notions of 'intactness' and of 'selective dissociations' needed to be replaced with a developmental notion of 'atypically developing trajectories' over time (Karmiloff-Smith, 1998; Karmiloff-Smith, Scerif *et al.*, 2003; Karmiloff-Smith, 2004). We focus here on how the linguistic trajectory in WS develops, arising initially from the unusual communicative and cognitive

profile in the development of infants and toddlers with the Syndrome.

Precursors to Language in Infants and Toddlers with WS

Much of the initial research on WS language focused on older children and adults, with little known about the early stages. More recent studies at four different labs in the United Kingdom, United States, and Italy have pinpointed a serious delay in the onset of WS language (Mervis and Bertrand, 1997; Nazzi *et al.,* forthcoming; Paterson *et al.,* 1999; Singer *et al.*, 1997; Vicari *et al.,* 1996; Volterra *et al.,* 1996). It is not uncommon to find children with WS of 4 or 5 years of age who produce levels of language typical of 18 to 24 month olds. Is the initial delay in getting WS language off the ground merely the late maturation of a set of language-specific genes, or are there more complex *developmental* reasons?

In our view, several cognitive and linguistic factors interact developmentally to cause the initial delay that affects the subsequent deviance in WS language development. Our studies show that infants with WS are some 10 to 20 months behind their typical control infants in segmenting words out of the speech stream (Nazzi *et al.,* 2003). This early difficulty, solved by typically developing infants at about 8 months, contributes to the WS delay. Furthermore, despite their abilities with dyadic interaction, infants and toddlers with WS are surprisingly atypical in triadic interaction and in their understanding of the referential function of pointing (Mervis and Bertrand, 1997; Laing *et al.,* 2002), one of the ways in which children normally learn new words. In addition, while they behave like controls in mapping perceptual similarities between objects, toddlers with WS are significantly poorer than controls at using linguistic labels to map identity of object categories (Nazzi and Karmiloff-Smith, 2002).

Language in Older Children and Adults with WS

It could be that the initial delay in language onset in WS is followed by a normal developmental trajectory, in other words that older children simply 'catch up.' This does not appear to be the case, however. Both behavioral and brain imaging studies of WS language processing make it empirically questionable as to whether any aspect of language – syntax, lexical-semantics, phonology, pragmatics, or discourse – is intact in WS, despite many claims to the contrary (e.g., Clahsen and Almazan, 1998; Pinker, 1999). For example, event-related potential studies suggest that brain activity to semantic, syntactic, and sensory features of spoken language are abnormally organized in adolescents and adults with WS. In normal adults and typically developing children of 9 years of age and older, ERPs to grammatical function words, e.g., articles, prepositions, conjunctions, show marked differences in latency, amplitude, and distribution, from those to semantic content words, e.g., nouns, verbs, and adjectives, (Neville, Coffey, *et al.*, 1993). Grammatical function words elicit a left anterior negativity early in the waveform, whereas content words elicit ERPs that peak somewhat later, are largest over posterior regions, and are bilateral or larger over the right than the left hemisphere. ERP differences to function words and content words have even been observed in infants as young as 20 months of age (St. George and Mills, 2001). In contrast, adolescents and adults with WS do not show ERP differences to function and content words, nor do they show left greater than right ERP asymmetries to the grammatical function words (Bellugi *et al.,* 1999a; Bellugi *et al.,* 1999b; Mills, 1998; Neville, Mills *et al.*, 1993, 1995; St. George *et al.,* 2000). Additionally, WS brain activity to words appears to be abnormally organized even at the level of sensory processing of the words. In WS, ERPs within the first 200 ms of the onset of the word show a unique pattern of components, with abnormally large bilateral positivities at 100 ms and 200 ms, which are not observed in a similar configuration at any age in normal development (Bellugi *et al.,* 1999b; Korenberg *et al.*, 2003; Neville, Mills *et al.*, 1995). These components are thought to be generated in the primary auditory cortex and may be related to a disproportionately large superior temporal gyrus (STG) and abnormal cell packing density in this region in WS (Hickok *et al.,* 1995; Holinger *et al.,* forthcoming; Galaburda *et al.,* 2003). Of particular interest is a report by Mills *et al.,* (2003a) showing that although adults with WS show abnormally organized brain activity to language, infants with WS display a normal pattern of asymmetries until about 3 years of age. However, by 3 to 4 years of age, ERPs to words begin to resemble the highly atypical pattern displayed by older children and adults with WS. Three years of age is also the time at which infants with WS show a marked increase in vocabulary development. This suggests that compensatory neural mechanisms linked to relative proficiencies in language processing may emerge at this point in development. Taken together, these studies provide neurobiological evidence against the notion of an intact, normally organized module for language processing in WS.

Despite growing evidence counteracting the claim for the intactness of language in WS, linguists of a

Chomskyan persuasion have tried to identify at least one aspect of WS language that is spared. For example, in a study comparing WS and Specific Language Impairment (SLI), Clahsen and Almazan (1998) argued for a double dissociation of innate mechanisms. Their assertion was that lexical memory is impaired in WS whereas syntax is intact, and that the opposite holds for SLI. Specifically, they claimed that individuals with WS display a deficit in forming irregular past tenses (e.g., keep-kept) but intact performance in forming the regular past tense (e.g., talk-talked). But this failed to hold when a broader, in-depth study of WS past tense formation was carried out on a much larger population (Thomas *et al.,* 2001). Indeed, it is not sufficient to demonstrate in any group that irregular past tense formation is poorer than regular past tense formation, because this is also true of some stages of typical development. Rather, it is crucial to demonstrate that the level of past tense formation is poorer than would be expected in WS for their actual level of language development. Our study showed that when verbal mental age was controlled for, the WS group displayed no selective deficit in irregular past tense formation and that their performance could be placed on the typical developmental pathway found in younger subjects. The results were more consistent with the hypothesis that the WS language system is delayed because it has developed under different constraints. Mervis and collaborators (e.g., Klein and Mervis, 1999) have also concluded that the best way to characterize WS language, even in adulthood, is that it has not developed normally and reveals patterns typical of much younger children.

Not only is WS language delayed, but it is becoming increasingly clear that the WS language system develops along a different trajectory compared to controls, relying less on semantics than in the typically developing children (Mervis and Bertrand, 1997; Thomas and Karmiloff-Smith, 2003). Although local semantic organization looks normal in WS in terms of priming effects (Tyler *et al.,* 1997) and category fluency (Scott *et al.,* 1995), global semantic organization remains at the level of young children and never reaches the mature state, even in relatively high functioning adults with WS (Johnson and Carey, 1998). Further studies of oral and written language also point to a reduced contribution of semantics in WS anguage development. For example, Karmiloff-Smith and collaborators found that when participants with WS monitor sentences for a target word, semantic information becomes available too slowly to be integrated with the real-time processing of syntax (Karmiloff-Smith *et al.*, 1998). A recent study of reading also pointed to atypical processing, showing that whereas WS participants displayed equal levels of reading for both concrete and abstract words, the controls found concrete, imageable words much easier to read (Laing *et al.,* 2001). Finally, in a non-word repetition study, participants with WS, despite a vocabulary test age of 8, behaved at the level of 4 to 5 year olds and were significantly less constrained by resemblance with meaningful words when repeating new words (Grant *et al.,* 1997). In sum, like very young children, the participants with WS were less influenced by the semantics of the words that the nonce terms resembled and relied more on phonology. Taken together, these different studies suggest that, unlike typical development, semantics seems to place less of a constraint compared to phonology (Laing *et al.,* forthcoming) in the way in which WS language develops over time.

The above discussion concerns lexical-semantic development in WS, but it remains a theoretical possibility that WS syntax is intact (e.g., Clahsen and Almazan, 1998; Pinker, 1999). There are, however, a number of lines of evidence to doubt this. First, vocabulary levels are usually better than syntactic levels, with both significantly below chronological age (Karmiloff-Smith *et al.,* 1997). Second, even in simple imitation tasks, participants with WS show significant deficits with complex syntactic structures such as embedded relative clauses (Grant *et al.,* 2000). Furthermore, even in simple grammatical concord in French, acquired easily by very young children, individuals with WS display serious deficits (Karmiloff-Smith *et al.,* 1997). The same applied in a study of Italian grammatical gender in which the WS group produced errors encountered at no age in typical development (Volterra *et al.,* 1996). Several studies (e.g., Klein and Mervis, 1999) make it clear that the real problems that people with WS experience with semantics and syntax are often superficially camouflaged by their good verbal memory.

It is in our view theoretically misleading and empirically inaccurate to claim that grammar is spared in this clinical population. Although WS grammar is indeed relatively proficient compared with some other clinical groups and relatively good compared with WS spatial deficits, most studies show that it is in fact no better than their mental age would predict. This does not mean that the WS cognitive architecture is uninteresting. On the contrary, there is in WS a mixture of delay, deviance, and asynchronies across the developing system. Researchers still need to understand why the language of people with WS language is initially so delayed and why, despite this, they develop surprising proficiency by adulthood compared to many other genetic syndromes with equal delay in early development.

Kay Williamson was born in Hereford, England, in 1935. After completing a B.A. degree in English at the University of Oxford, she moved to Nigeria with a Leverhulme Research Scholarship, where she began research on the Ịjọ language cluster and later became an Assistant Lecturer in Phonetics at the University College of Ibadan. She later studied linguistics at Yale University, where she received her Ph.D. in 1964.

After further research on Ịjọ with a fellowship from the American Council of Learned Societies, she

taught linguistics at the University of Ibadan, where she became a Professor in 1972.

In 1977, she moved to the University of Port Harcourt in Nigeria, where she taught Linguistics and Nigerian Languages until she retired in 2000.

She held the UNESCO Chair in Cultural Heritage at the University of Port Harcourt, Nigeria until her death. With Nigerian colleagues, she initiated the Rivers Readers Project, which encouraged students to study their own languages, to develop orthographies and reading materials. Through the Rivers Readers Project, primary school books have been published in all the languages of Rivers State.

She is a founding member and has been a council member of the West African Linguistics Society and the Linguistic Association of Nigeria. Kay Williamson is a specialist in Nigerian languages and comparative Niger-Congo. She has published on Ịjọ, Igbo, various other languages of the Niger Delta, and the classification of Benue-Congo and Niger-Congo. She wrote the Niger-Congo and the Benue-Congo overview in J. Bendor-Samuel's Niger-*Congo* (1989) and is co-author of the chapter on Niger-Congo in B. Heine and D. Nurse's (2000) *African languages: an introduction*.

Kay Williamson was an eminent linguist and a very special person. Her two greatest contributions are in comparative West African linguistics and in local language development. This was very influential both for the products developed, and for the awareness and legitimacy it gave to many local languages.

She has inspired and taught whole generations of students to become linguists like herself: competent, kind, and able to apply her skills to help new generations to a better image of themselves, their family, people, and nation.

Kay Williamson passed away on the 3rd January, 2005, as she was approaching her 70th birthday.

Jost Winteler was born in Kerenz-Filzbach, a village in the Swiss canton of Glarus. He was the son of a school teacher and therefore was not only familiar with the local Swiss German dialect but also with standard (Swiss) German. He studied philology in Jena, Germany, where the Neogrammarians Berthold Delbrück and Eduard Sievers were among his teachers. In his famous doctoral thesis, published in 1876, he described his native dialect of Kerenz. This thesis served as a model for generations of dialectologists. In Switzerland, Professor Winteler taught at several high schools, and from 1884 on, also at the cantonal school in Aarau, attended by Albert Einstein in 1895–1896. The young Einstein stayed with the Winteler family; from this evolved an intellectual and a personal, life-long relationship strengthened by Winteler's son Paul marrying Einstein's only sister Maja in 1910.

taught linguistics at the University of Ibadan, where she became a Professor in 1972.

In 1977, she moved to the University of Port Harcourt in Nigeria, where she taught Linguistics and Nigerian Languages until she retired in 2000.

In Switzerland, Professor Winteler taught at several high schools, and from 1884 on, also at the cantonal school in Aarau, attended by Albert Einstein in 1895–1896. The young Einstein stayed with the Winteler family; from this evolved an intellectual and a personal, life-long relationship strengthened by Winteler's son Paul marrying Einstein's only sister Maja in 1910.

Table 1 J. Winteler's relativity of conditions shown by formalizing his examples of consonants

Type of feature	*'Soft' languages*		*'Hard' languages*		*Swiss German dialects*	
	Lenis	*Fortis*	*Lenis*	*Fortis*	*Lenis*	*Fortis*
Essential	+voiced	−voiced	−tense	+tense	−tense	+tense
Accidental	+long	−long	+long	−long	−long	+long
	−tense	+tense	−voiced	−voiced	−voiced	−voiced
Examples	{[b], [d], [z], [r]}	{[p], [t], [f], [s]}	{[b̥], [d̥]}	{[p], [t], [f], [s]}	{[b̥], [d̥], [f], [s], [x]}	{[f:], [s:], [x:]}

The 'sound physiology' as a method founded by Jost Winteler and his teacher Eduard Sievers stood in the context of the Neogrammarians' orientation to natural sciences. As E. Sievers (1876: 1) put it: analyzing the acoustic nature of sounds is a matter of physics while physiology furnishes information about the activity of the organs producing language sounds. Despite Ernst Brücke, a precursor of phonetic description, this method was sensational in 1876, since it was contrary to the Neogrammarians' sound description drawn from written records. Winteler (1876: 37ff.) analyzed his own articulation of the dialect sounds. To him 'auto-phonography' was the only reliable basis of sound physiology. In order to describe the results, he created a special phonetic notation system.

Winteler's work was well accepted by the Neogrammarians, mainly because studies of present-day dialects were considered important for comparative linguistics, as they can be observed directly (cf. Kohrt, 1984: 9). In the view of the 20th century structuralists, the cause for praising Winteler was his prestructural approach: he noticed that there are sounds with and others without the capacity to change meaning, not demanding, however, two different disciplines of sound description: *phonology* versus *phonetics*, respectively. It was rather a demonstrative method to explicitly show the difference of sound (Kohrt, 1984: 22ff.). In Winteler's thesis, one can furthermore find minimal pairs (e.g., Winteler, 1876: 20): *tsex & zehn* ('ten'): *tsexx&* (plural of *tsexx* m.), Schafzecke ('sheeptick'). Purely structural terms were used already (Winteler, 1876: 19ff.), such as *Lautgegensätze* ('contrasts of sound'), *(Sprach-)Bau* '(linguistic) structure', and *Konsonantensystem, Sprachsystem* ('system of consonants, of language').

The speculation over Winteler's influence on Einstein's theory of relativity stemmed from two reasons: Winteler was Einstein's mentor and rooming house owner, and Winteler (1876: 27) made a remark on the *Relativität der Verhältnisse* ('relativity of conditions' or 'configurational relativity') (Jakobson, 1972: 75). Jakobson exaggerated Winteler's influence on Einstein while others were more reserved (cf. Kohrt, 1984: 82ff.). Winteler's single remark was purely linguistic, its context, however, a bit confused. As a result of his studies, Winteler concluded that certain linguistic features (a, b, etc.) are more characteristic of language group A than of others and that other features are more characteristic of language group B than A. In his examples, he distinguished what he called essential and accidental features in describing a 'Lenis' (such as {[b], [d], [g]}) and a 'Fortis' (such as {[p], [t], [k]}) as realized in:

1. soft languages (e.g., in Low German dialects, the essential feature is *voiced*)
2. hard languages (e.g., in Upper German dialects, the essential feature is *tense*, i.e., spoken with high pressure and energy)
3. Swiss German dialects (the essential features are *tense* and *duration*).

As varying conditions lead to a different application of these features to language systems, the configuration of these features is relative. All dialects shown in the table differ from each other for this reason (Table 1).

Witness Examination

J Cotterill, Cardiff University, Cardiff, UK

© 2006 Elsevier Ltd. All rights reserved.

Role and Status of Witness Examination in Trial-by-Jury

The adversarial jury trial represents a highly structured legal process, involving a number of distinct phases, as illustrated in Figure 1.

After the jury selection or *voir dire* process, lawyers from each side have the opportunity to present monologic speeches to the jury, in the form of opening statements. One of the principal aims of the opening statements, which begin the evidential phase, is to allow both sides to present an outline of the fundamental questions in the case from their respective positions. The entire trial may be considered to be a macro-level question-and-answer sequence, responding to the essential question: Is the person presented before the court as the defendant guilty or not guilty of the charges brought against him?

An attempt to answer this question comes in the form of elicited testimony from a range of lay and expert witnesses called to the stand. If the prosecution-elicited answers are deemed adequate by the jury, then the 'burden of proof' is said to have been fulfilled; conversely, if the defense version of events is favored by the jury, the issue of 'reasonable doubt' is invoked. The ultimate judicial 'answer' (i.e., the verdict) is delivered by the jury in the final judicial phase of proceedings.

Figure 1 Adversarial trial phases.

The witness examination phase of the trial is the focus of attention in this article. It represents the site of attempts by both sides to provide plausible and credible responses to the issues presented in the opening statements. This phase of the trial is usually the most protracted, involving a cycle beginning with the calling of a new witness, the examination, cross- and re-examination of that witness, and ending with a judicial invitation for the witness to 'step down.' The cyclical nature of witness examination is indicated by the circular lines in Figure 1. There is circularity both *between* and *within* witnesses; witnesses are called by their own 'supportive' lawyer first to provide 'direct' or 'examination-in-chief' evidence and then by opposing lawyers, where their evidence is scrutinized by the other side, during 'cross-examination.' This process may be followed by 're-direct examination' and then by 're-cross examination,' if lawyers from either side wish to pursue particular issues in further detail. Such questioning will alternate as shown in Figure 2.

Conflicting Accounts in Direct and Cross-Examination

Linguists, lawyers, and applied psychologists have all conceptualized the jury trial as a process of storytelling (see *inter alia* Maley, 1994; Jackson, 1995; Brooks and Gewirtz, 1996; Hastie and Pennington, 1996; Bruner, 2002). Viewed in this light, a trial may be seen to comprise two (or potentially more) competing narratives, elicited from witnesses, structured by the prosecution and defense, and submitted to the critical evaluation of the jury.

Figure 2 Maximal structure of witness examination.

The trial is therefore the telling not of a single story, but rather of a number of alternative versions from a variety of (conflicting) perspectives (Harris, 2001; Cotterill, 2003). The name often given to the jury in adversarial trial procedure, that of the 'factfinder,' is actually something of a misnomer, because the jury is not asked to find the truth, but rather to adjudicate among more and less plausible narrative accounts. In a trial, these constructed narratives are both multiple and multiperspectival, involving the presentation of many of the same crime 'facts' in the form of alternative and competing narrative versions, or "secondary realities" as Gibbons (2003: 147) terms them. Each of these witnesses may have a potentially conflicting version of events to narrate, and each may have a different perspective and interpretation of the events that they recount, as Scheppele (1989: 2085) points out:

> The same event can be described in multiple ways, each true in the sense that it genuinely describes the experience of the storyteller, but each version may be differently organized and give a very different impression of 'what happened.'

Elicitation of Evidence during Witness Examination: Power Asymmetry in Lawyer-Witness Interaction

Perhaps the most significant constraint on the construction and presentation of these multiple and conflictual versions of events is the fact that this evidential picture is built up by means of question-and-answer adjacency pairs in a dialogic interaction between lawyer and witness that explores the events and circumstances of the crime under scrutiny.

The stories told in court are not narrated by the 'primary knower' (Berry, 1981), the witness, but rather are elicited by means of the lawyer's questions. The lawyer was not present at the crime scene; the witness, who conversely may have been present, cannot typically claim to possess the same courtroom storytelling skills as the lawyer. The result is a mutual dependency, where both parties need the other to enable the story to be told effectively within the confines of the trial framework.

From a discourse as well as a legal perspective, the courtroom is a highly role- and rule-governed environment. Not only are the various participants bound by laws and protocols that govern their physical behavior and demeanor but there are also clearly defined controls on their language. These linguistic constraints include such factors as the *quantity* of talk allocated to each participant – in other words the relative distribution of talk among the judge, lawyers, and witnesses – and the *nature* of that talk, including interaction, turn initiation, topic management, and the differential use of declaratives, interrogatives, and imperative forms in court.

Whereas in casual conversation, the management of turn-holding is a highly skilled, locally negotiated matter in which participants attempt to negotiate the smooth transition of the turn from one speaker to the next, thereby avoiding face-threatening clashes, in the courtroom context, such considerations of politeness, face, and cooperation are less significant. This is because the default position in power-differential interaction is that the more powerful of the interactants may hold the floor until he or she is ready to give it up. Then, and only then, is it possible for the less powerful participant to join in, at the discretion of the other, more powerful, speaker.

Thus, in the trial-by-jury system, the familiar features of conversational management are, as Matoesian (1993: 79) notes, "systematically transformed and exploited to manage the powerful interests and interactional contingencies of legal disciplinary regimes." Although casual conversational talk is managed relatively spontaneously with turn-taking negotiated at a local level, in the courtroom, many of these norms are pre-determined, with pre-allocation of turns and turn-types the rule, rather than the exception (see Atkinson and Drew, 1979 for a detailed description of the turn-taking system in court).

Much of the literature on the language of the courtroom over the past two decades has focused on the elucidation and exemplification of the asymmetry inherent in courtroom questioning. A succession of studies conducted by researchers such as Atkinson and Drew (1979), O'Barr (1982), Bogoch and Danet (1984), Woodbury (1984), and Luchjenbroers (1997), have all concluded that the courtroom is a highly power-asymmetric interactional context, resulting in unequal turn-taking allocations and differential questioning and speech act rights, with lawyers being variously described as 'controlling' (Woodbury), 'coercive' (Bogoch and Danet), and 'restrictive' (Luchjenbroers) in their questioning of witnesses. This control of the witness and their testimony occurs in both direct and cross-examination, although cross-examination is in general significantly more coercive than its 'direct' or 'examination-in-chief' counterpart.

Analysis of trial data reveals endless examples of moments when witnesses are reminded of these interactional rules, as in the following example where the witness is put firmly in his interactional place, subordinated to both judge and lawyer. These extracts are drawn from adversarial criminal trials in the United Kingdom, United States, and Australia, dating from the early to the late 1990s. Each is tagged with the country of origin, and all names and places have

been made anonymous to maintain the confidentiality of the participants.

Extract 1 (U.S.):
Judge: Hold on, Mr. D., would you allow Mr. A. and the other lawyers to finish asking the question before you start to answer?
Witness: OK. Yes, sir
Judge: See, you just did it right now.
Witness: I'm sorry.

Even the court reporter may be brought into the equation as a motivating factor for encouraging adherence to the interactional rules:

Extract 2 (U.S.):
Judge: Excuse me.
Witness: I'm sorry.
Judge: Mr. B., if you would, would you allow Ms. C. to finish asking you the question before you start to answer, because the court reporter is having a hard time because you are both trying to talk at the same time.
Witness: I shall.
Judge: Okay. You will get out of here a lot quicker if we do it that way.
Witness: Thank you.

In the examination of witnesses, conducted predominantly by means of dialogic question-and-answer sequences, the lawyer takes on the role of questioner, a role again typically associated with the more powerful participant in power-asymmetric dyads. The lawyer can therefore be seen to function predominantly in the role of initiator of inquiry and evaluator of witness response, roles that are associated most frequently with interactionally powerful participants.

In contrast, the witness's interactional options in court are severely limited. The principal role of the witness is to provide appropriate responses to the questions of the lawyer (and, on occasion, the judge), occupying the role traditionally reserved for less powerful interactional participants, such as the suspect (in police interviews), the patient (in talk in medical settings), or the candidate (in a job interview).

The default requirement is for the witness in court to provide 'preferred' second-part responses – answers to the lawyer's questions – that adequately satisfy all four of the Gricean maxims. When they take their oath before testifying, witnesses swear to tell "the truth (maxim of *quality*), the whole truth (*quantity*), and nothing but the truth (*relation*)," thereby ostensibly satisfying the first three of the four criteria for optimally cooperative talk (Grice, 1975). By going through the legally binding performative utterance of the oath, witnesses effectively agree to be 'cooperative' participants, under threat of perjury charges.

The fourth maxim, of *manner,* ('avoid obscurity and ambiguity') is managed by means of the requirement for witnesses to be 'responsive'; in other words, to answer the question to the satisfaction of both lawyer and judge. If a 'responsive' answer is not forthcoming, the judge may rule the witness 'nonresponsive' and (under the threat of contempt charges) may oblige the witness to provide a more acceptable response, even down to prescribing its form as a restrictive yes/no response, as in the following example:

Extract 3 (U.S.):
Lawyer 1: Objection, your Honor. Pardon me, sir. This is nonresponsive.
Lawyer 2: Your Honor, this is – he's responding seems to me.
Lawyer 1: The question called for a yes or no answer.
Judge: Sustained. The witness may answer yes or no.
Witness: I'm sorry, I've forgotten the question.

In summary, witnesses are poorly placed in the interactional hierarchy of courtroom talk; they have no control over the talk of other participants in the trial process and only a very limited control over their own contributions. Witnesses are cast as respondents to questions, and attempts by them either to initiate talk or to provide evaluative feedback are penalized. Questions from witnesses are rare and are limited typically to requests for clarification.

Despite these general tendencies, it is important to acknowledge the fact that not all witnesses contribute to the trial narrative in the same way; there are significant variations between direct and cross-examination strategies, both in terms of lawyer's questions, and the responses of the witness. Each of these strategies is now discussed in turn.

Questioning Strategies in Witness Examination

Direct Examination Questioning

Direct examination questioning is characterized by broad *wh-* type questions (who, what, when, where why, how) that give witnesses the opportunity to provide evidential information. This is particularly true of the first stage of direct examination, as in the following illustrative extract:

Extract 4 (UK):
Q: *Could you give the court your full name please, sir?*
A: My name is R.G.

Q: Can I ask you to keep your voice up and to aim at the back row of the jury, which will ensure that everybody hears what you say. Mr. G., are you still employed as a Station Clerk at Nowhere Police Station?
A: Yes.
Q: *And approximately how long have you worked there for*?
A: About seven years.
Q: *During the period 1995 to 1997 how many civilian clerks were there at Nowhere Police Station*?
A: There were three civilian clerks.
Q: *That's yourself obviously, and who else*?
A: Mrs. B. and Mr. F.

In this extract, the witness is asked a series of information-seeking (as opposed to clarification-seeking) questions relating to his name, the nature and duration of his employment, and the number and names of his colleagues. The witness responds with brief but informative answers, allowing the testimony to move on apace.

In contrast, some direct examinations allow witnesses to produce relatively lengthy contributions, as in the following example:

Extract 5 (UK):
Q: And jumping on many, many years ahead, the jury has seen a letter that you wrote which is found at DOB/7, which makes reference to giving your card to a certain person?
A: Yes.
Q: In the first line, and who was that person?
A: E.
Q: E. Going back to E, *what sort of opportunities were offered to you in regard to the music business*?
A: He asked me if I wanted to do some promotional work for the company, his own company and then when he actually became part of another company if I still wanted to continue working for him; it was on a part-time basis as and when he wanted me to work for him.
Q: Did there come a time through E when you were offered employment in London?
A: Yes.
Q: *And how was that*?
A: He told me that his brother was setting up a similar company to himself, doing dance music promotions, and he said if you come along on this day this job will be there. Then I ended on moving from B. to L., arrived for the first day of the job and the job wasn't actually there.

In this example, the witness produces two extended narrative turns, consisting of more than 50 words each. These relatively lengthy contributions are prompted by the open questions, "What sort of opportunities were offered to you in regard to the music business?" and "And how was that?," respectively.

Although questioning in direct examination is generally less restrictive than in cross-examination, there is still a tendency for direct examination lawyers to control testimony elicitation through the use of both response-restrictive yes/no questions (e.g., 'was the car red?') and disjunctive questions (e.g., 'was the car red or blue?'):

Extract 6 (UK):
Q: When he was around at your premises, no doubt, you talked of this and that. *Would he ever do any drawing*?
A: No, sir, not on the premises, although he has done a number of paintings for me at his flat in G. Park and then brought them round, and I have paid him sums of money for each painting.
Q: *Would the drawings be of people, places, or both*?
A: People.
Q: *What people did he draw*?
A: He done a picture of me when I was 17 taken from a photograph. He done a picture of S. S. from about a year previous sitting on the sofa. He also done a picture of S. S. from a naked photograph that was taken in Amsterdam. He also done a painting of a boy named A. C., one of a facial portrait and another one of him standing holding a cat taken from a photograph in my garden. He also done one of my friend S.S.'s deceased grandmother as a birthday present for his stepfather.
Q: *All of these pictures done from photographs*?
A: Photographs. Yes.
Q: I follow. *He would do them away from your home*?
A: Yes. That is correct.

Extract 6 illustrates the way in which the direct examination lawyer integrates into his questioning style both open questions, such as 'What people did he draw?,' with more closed yes/no type questions (Would he ever do any drawing? All of these pictures done from photographs?) and equally response-restrictive disjunctives (Would the drawings be of people, places, or both?).

The effect of such questioning strategies, even during direct examination, is to control and constrain the witness's freedom to respond. As Tiersma (1999: 159) put it, "With a narrative, the storyteller herself decides how to tell her tale, while a question-and-answer format allocates control to the questioner, in this case, the examining lawyer." This next illustrative extract taken a British domestic violence case (see Cotterill,

2004), demonstrates the role of the lawyer as primary narrator of the story:

Extract 7 (UK):

Q: I think it is the position – and I would invite you to you confirm this – that your relationship with the defendant really ran into terminal difficulties in about February, 1996? Last year?
A: No. It started in all about Christmas time.
Q: That was the final stage of your relationship – if you like, the last few months – but would it be fair to say that your relationship, generally, has been quite a stormy one with the defendant?
A: Yes.
Q: You would argue?
A: Yes.
Q: You would fight?
A: Sort of.
Q: The defendant would leave?
A: Sometimes.
Q: Then you would have him?
A: Yes.
Q: That happened on many occasions?
A: Yes.

On detailed inspection, it is apparent that the lawyer is in fact the principal narrator of this account. He is responsible for topic-raising in each of the propositions concerned (the nature of the complainant's ongoing relationship with the defendant, their respective patterns of behavior, the frequency of violent incidents, and so on). In contrast, the witness is primarily limited to the role of providing confirmatory responses, typically in the form of a single-word affirmative – 'yes.' This is of course made possible by the lawyer's use of closed, response-restrictive, yes/no questions.

Not only is the lawyer responsible for producing the majority of the narrative but the witness's attempts to contradict the unfolding (lawyer-initiated) narrative are also largely unsuccessful; although the lawyer begins by hedging his initial contribution with" I think . . ." and "I would invite you to confirm this . . ." in the first line, and later (in line 6), asks, "Would it be fair to say . . .?," using markers indicative of hesitancy, doubt, or at least politeness; in offering the other speaker a turn, he responds to her attempt to correct the date from February to "about Christmas time" (line 4) with a dismissive gloss of "the last few months" and "generally" (lines 5 and 6).

In Goffman's (1981) terms, this interaction illustrates the separation of the speech production roles of animator, author, and principal. The animator in this instance, as the one who produces or gives voice to the message being conveyed, is clearly the lawyer. The author is the person responsible for the selection of words and sentiments that are being expressed, again a role taken on by the lawyer. The principal is the person whose position or beliefs are being represented and is also the one who is held responsible for whatever position is being presented. The role of principal in courtroom interaction is ostensibly taken by the witness, although, as we have seen in this initial extract, her actual participatory role is relatively minor. Indeed, her overall contribution only amounts to 15 words of a total of 102, with an average turn length of only 2.1 words, compared with a 14.6 words per turn average for the lawyer. As Duranti (1997: 297) notes, "Although speakers often assume all three roles [animator, author, and principal] at the same time, the roles need to be distinguished in more cases than we might think." In the context of courtroom interaction, even though it is apparently the witness's account of the crime that is being elicited, this narrative is invariably voiced by the lawyer.

In addition to providing propositions along with a request for confirmation, often called 'requestions' (after Danet and Kermish, 1978), it is also possible for lawyers to restrict the responses of the witness by providing an indication of the extent of the response within the question. The following two British trial examples illustrate this phenomenon:

Extract 8 (UK):

Q: Why was that? *Very shortly.*
A: *Summing up*, I think he was a little bit – I don't know if frightened is the word. It possibly is – frightened of coming round, because obviously he had had a few comments made about him to him to his face about his appearance by Mr. T. S. I was not as friendly towards him as I was when he first came round, possibly that stopped him, although he suffered with depression. He told me he suffered with depression. He was very withdrawn as I have explained earlier and I thought. In my opinion he felt it would be best left not coming round and he did not do so.

Extract 9 (UK):

Q: Did you have an accident?
A: Yes, on 1st April 1989.
Q: What was the result of that accident? *I need not ask you the details*, Mr. C.?
A. *In short*, an injury to the lower spine resulting in, eventually, no bladder control, pains to the lower left-hand side of the hip and body, numbness, pins and needles. Just a deteriorating condition. I have been told it is referred to as Coxaphenia and spondylitis, which is a deterioration of the spinal cord.

The direction provided by the two lawyers to respond 'very shortly' and without detail results in relatively compact and information-dense responses from each respective witness. Interestingly, both witnesses also articulate a textual acknowledgement of the request at the outset of their responses – witness 1 in Extract 8 answering by 'summing up' and witness 2 in Extract 9 providing his response 'in short.'

The majority of research into courtroom direct and cross-examination has found that witnesses are effectively prevented from 'telling their own stories,' with the blame placed squarely at the door of the question-and-answer format that prevails in the Anglo-American adversarial system. This seems to be true even in the case of direct examination lawyers.

There may, in fact, be sound psychological benefits in such elicitation strategies for narrative-constructing direct examination lawyers. Research by O'Barr (1982) and others has suggested that tight and coherent narrative versions are preferred by jurors over loose and disjointed testimony elicited by means of more turn-generous open questions. Witnesses producing coherent and chronological accounts tend to be considered more truthful, competent, intelligent, and convincing than those who provide more 'fragmented' versions. Jackson (1995: 400) argues that "counsel must decide, in effect, who can tell the story better – the witness (who has the benefit of 'authenticity,' but perhaps lacks the enunciative ability) or counsel, who lacks the authenticity of a witness, but may have better enunciative ability."

Cross-Examination Questioning Strategies

In cross-examination, witness testimony is constrained even more tightly. Studies by Woodbury (1984) and Luchjenbroers (1997) have shown that cross-examination is characterized by closed, response-restricting questions.

Maley and Fahey (1991: 7) found that confirmation-seeking questions were used in 75% of exchanges, thus enabling counsel to "assume the role of story-teller in the trial process." In a later article, Maley (1994: 36–37) cites the following example:

Extract 10 (Aust):

Counsel: And I suppose it would be fair to say that as they came to recognize the extent of your knowledge about overseas drugs, so they became more and more interested?

Witness: No, that would be incorrect. They already knew where I stood, much prior to July of 1982.

Counsel: You say that their intelligence was sufficient to let them know how important you were even before you spoke to them?

Witness: They had been following me . . .

Counsel: Is that right or not?

His Honor: Just a moment, Mr. B. I am allowing the witness to answer that question. . . .

Counsel: Would you say what you were saying, Mr. C.?

Witness: They had been following me . . .

In this extract taken from an Australian courtroom, Maley noted that the lawyer's question to the witness relating to the police's intelligence about his activities is phrased "in the form most favored by cross-examining counsel: a declarative with a rising tone which seeks confirmation, not information, as a response" (1994: 37).

In the same witness's parallel direct examination, Maley discussed the comparatively "congruent and cooperative" pattern of question and answer:

Extract 11 (Aust):

Counsel: After having given those documents to Mr. H., did you see Mr. H. again?

Witness: Yes I did.

Counsel: When was that?

Witness: About the second or third week of June

Counsel: Did you have a conversation with him regarding M.?

Witness: Yes I did.

Counsel: What did you say?

Witness: I said to him '. . .'

Counsel: Then Mr. H. said something to you?

Witness: That is correct.

Here, since the lawyer is not permitted to elicit evidence via 'leading' questions (questions that presuppose a particular response – a strategy permitted in cross-examination; see Hobbs, 2003), the interaction can be seen to be "alternating between indefinite polars" ("Did you then say something?") and open information-seeking questions ("What did you say?"; Maley, 1994: 38).

A further linguistic strategy employed particularly by cross-examining lawyers is the use of tag questions, which generally introduce leading questions. Tiersma (1999: 165) provides the following examples:

You ate broccoli last night, *didn't you*?
You ate broccoli last night, *isn't that correct*?
It is true, *is it not*, that you ate broccoli last night?

Danet and Bogoch (1980) showed that 53% of all questions in their cross-examination data were in the form of declaratives with either tags or rising intonation, compared to only 9% of questions in direct examination. The following example from the O. J.

Simpson criminal trial (see also Cotterill, 2003) shows the use and distribution of tag questions in cross-examination:

Extract 12 (U.S.):

Q: When you went out to where the glove was eventually pointed out to the other detectives, how long did you spend there before you went back to talk to them?
A: Ten, 15 minutes totally.
Q: What did you do for 10 to 15 minutes on that scene?
A: Looked for a victim or a suspect.
Q: Now if that glove had been there where you say you found it, it would have been placed there by someone involved in the homicide; *isn't that conclusion compelled?*
A: I would assume that, yes.
Q: That would be a vicious killer of some sort, *would it not*?
A: Yes.
Q: And you hung around for 15 minutes with no back-up and no vest doing something, *is that correct*?
A: No it isn't.
Q: And their tracks might still have been there when you made that discovery, *correct*?
A: I didn't see anything, but they could have been.
Q: And you could have taken the detectives on the outside of the fence and shown the flashlight through it to point out the glove, if you had chosen, *could you not*?
A: No. I think that would have been very difficult.

During this piece of trial data, in which the cross-examining lawyer is trying to promote the view that the police officer was behaving suspiciously and may have deliberately contaminated evidence at the crime scene, the lawyer uses tag and tag-like questions with both positive and negative polarity to suggest a series of scenarios that construe the police officer's behavior as counterintuitive and therefore suspect. Even though the officer contradicts the version put forward by the lawyer on two occasions ("No it isn't" and "No. I think that would have been difficult"), the impact of the lawyer's leading questions is still considerable.

Although this witness is fairly robust in his resistance to this type of questioning, there are significant concerns about the extent to which less competent witnesses are able to cope with such verbally assertive or even aggressive questioning strategies. Such groups of what are termed in the United Kingdom 'vulnerable witnesses' include victims of rape and sexual assault (Matoesian, 1993; Conley and O'Barr, 1998; Ehrlich 2001; Matoesian, 2001; Ehrlich, 2002), non-native speaker witnesses (see Berk-Seligson, 1999, 2002; Hale, 2004), child witnesses (Aldridge and Wood, 1998; Brennan, 1994; Walker, 1999), and witnesses whose cultural background clashes with that of the courtroom; for example, Aboriginals in Australia (Walsh, 1994; Cooke, 1995; Eades, 1995; Walsh, 1995; Cooke, 1996; Eades, 2002, 2004).

There are disturbing signs that the most controlling questioning strategies seem to be reserved for the most vulnerable members of society who come before the court, either as defendants or as victims of crime. These vulnerable people include not only those witnesses discussed above but also individuals with psychological or learning difficulties. Controlling questions seem to be used more commonly with these types of witness, and they also seem to yield higher coercive returns for the lawyers who employ them. Discussing this tendency, Tiersma (1999: 167) concludes

> It is troubling that this strategy is most likely to be effective with the socially and economically weakest members of society. One would hope that judges are aware of the problem and use their power as neutral arbiters to minimize its impact.

Role of Lexis in the Courtroom

It is not only question forms and sequences that affect the elicitation of evidence from witnesses on the stand; lexical choices also play a significant role in how testimony is elicited and conveyed to the jury.

Perhaps the most famous study that illustrates the importance of lexical choices in the depiction of forensic events was conducted by the psychologists, Elizabeth Loftus and John Palmer (1974). They demonstrated that, when people watch a film of an accident between a car and a van and are then asked to estimate the speed the car was traveling at the moment of impact, their responses are determined by the choice of verb used in the eliciting question; consequently, eyewitnesses asked 'how fast was the car going when it *crashed* into the van?' estimate consistently higher speeds than those asked 'how fast was the car going when it *hit* the van?' Their study also showed that forensic descriptions using words associated with violence, such as 'fight,' are more likely to lead to a conviction than more neutral words, such as 'incident.'

In the courtroom context, Brenda Danet (1980) discussed the use of no fewer than 40 different formulations to describe 'the products of conception.' In her data, taken from the U.S. trial of a doctor who had carried out a late abortion, *baby* and *fetus* were particular terms used by the prosecution and defense, respectively. The prosecution argument was constructed around the life (and death) of a *baby* and therefore represented a case of manslaughter, whereas the defense conceptualized the case in terms of a *fetus*.

Thus, the defense argued, because the fetus was incapable of independent life, there could have been no crime of manslaughter committed against it, rendering the trial inappropriate and unnecessary. The lexical stakes were considered sufficiently high in this case that the lawyer defending the doctor sought and was granted an order barring the use of a number of terms, including the emotive *smother*, *suffocate*, *murder*, and *baby boy*, all of which were disallowed by the judge on the grounds that the connotations of their use were potentially 'prejudicial.' In the end, the jury agreed with the prosecution formulation of the victim as *baby*, and the doctor was convicted of manslaughter. This case clearly illustrates the power of semantic categories and labels and their connotational force.

Drew (1992: 489) discussed lexical choices in a rape trial in which the lawyer argued that the initial meeting between defendant and plaintiff took place in a *bar*, suggesting that a bar is a place for people to pick up partners for casual relationships. The defense, in contrast, preferred to refer to it as a more 'respectable' *club*:

C: And you went to a *bar* in Boston, is that correct?
W: It's a *club*.
C: It's where girls and fellas meet, isn't it?
W: People go there.

Cotterill (2004) also explored the role of lexis in creating nuances of meaning for the jury in sexual assault and domestic violence cases, concluding that lexical representations of such crimes contribute to a widespread sense of injustice in the cross-examination of victims of these types of offenses.

Lawyers are able to use lexis to construct elaborate scenarios through the conscious manipulation of 'conceptual perspective' (Clark, 1997), defined as "the speaker's presentation of an object, relation, or event, through choice of words, to the addressee, such that some properties of the referent are included and others excluded by each choice" (Clark, 1998: 5). The ultimate impact of such representations is of course dependent upon the jury understanding the connotational loading of the lexical items selected.

Conclusion

This article outlines the interactional dynamics of witness examination in the adversarial courtroom, focusing on narrative and questioning styles, as well as the importance of lexical choice in the representation of crimes, their victims, and perpetrators. Any analysis of courtroom language is inevitably complex and multilayered, but the discussion presented here represents a summary of some of the key studies in this fascinating area of language and law. The adversarial trial context provides a rich source of data for linguistic analysis because all of its key practices are articulated through language. By scrutinizing such practices from a linguistic perspective, it is possible to elucidate the mechanisms of power and persuasion inherent in trial-by-jury in general and in witness examination in particular.

Wittgenstein, Ludwig Josef Johann (1889–1951)

W A de Pater and P Swiggers, Katholieke Universiteit Leuven, Leuven, Belgium

Ludwig Wittgenstein, one of the most influential philosophers and, in terms of general impact, thinkers of modern times, was born in Vienna on April 26, 1889. He was one of eight children in a mixed Catholic and Protestant (earlier Jewish) family, which intensively participated in the cultural and economic life of Vienna at the turn of the 19th/20th century, characterized by cosmopolitanism, by a suffocating bourgeois mentality (which also explains the rise of psychoanalytic treatments in society of that time), and by an unequalled theater and music life. Wittgenstein's

father, after having been a wool merchant, had established himself in Vienna as the director of a large steel company, and the family enjoyed a luxurious life, albeit overshadowed by oppressing and depressing paternal authoritarianism. The children were all endowed with artistic, technical, and intellectual skills, but seem to have experienced problems in psychological development and social adaptation; three of Ludwig's brothers committed suicide, and Ludwig's own life was characterized by constant imbalance in developing his own personality and in adapting to life in society. Wittgenstein received his first education in his parents' palatial home in Vienna, and showed remarkable technical skills (as a young boy, for example, he constructed a sewing machine). He was sent to a Gymnasium in Linz (1903–1906), and then to the Technische Hochschule in Charlottenburg (Berlin), where he stayed for two years. In 1908 he went to study at the University of Manchester in England, where he started doing aeronautical research; he designed a jet reaction engine and a propeller. Until then his interests had been in physics and in technology, but seeing how much mathematics was involved in both, he soon became interested in the philosophical foundations of mathematics. Having heard of the existence of Russell's *Principles of mathematics* (1903), Wittgenstein established contact with Russell and, on the occasion of a trip to Germany, with Frege. In the academic year 1911–1912 he enrolled at Cambridge University in order to study with Russell, on whom he left a deep impression. While at Cambridge he laid the basis of his logical views; he also spent much time performing music and doing experiments on rhythm in music.

During World War I, Wittgenstein was an officer in the Austrian army; in November 1918 he was taken prisoner by Italian troops and was held captive for some months in Italy. During wartime he had been systematizing his ideas on logic and philosophy; the resulting manuscript was sent to Russell (who discussed it with Wittgenstein in Holland in December 1919) and was published (in German) in 1921. This *Logisch-philosophische Abhandlung* (containing 526 decimally ordered short paragraphs) was subsequently translated into English and was published in 1922 with an introduction by Russell, under the title *Tractatus logico-philosophicus*. The book, which was the only philosophical book Wittgenstein published during his lifetime (in 1926 he also published a children's dictionary for use in primary school), is an important contribution to philosophy, and more particularly to the theory of logical atomism, which Russell had been developing for some years and which holds that there are only atomic facts (the connections made through words like 'and,' 'or,' 'if … then' are only logical manipulations), and that these can be analyzed exhaustively in terms of particulars, properties, and relations. Written in the form of a list of theses or statements, the *Tractatus* proposes a 'picture theory': our sentences have meaning because (and only insofar as) they are pictures of reality. Reality consists of facts (*Tatsachen*), and facts exist by virtue of being realized states of affairs (i.e., reality, or 'the world,' is everything that is the case); states of affairs (*Sachverhalte*) are nothing else but configurations of things (*Gegenstände*; *Dinge*; *Sachen*). Our thoughts (thinking has a 'factual' content, contrary to imagination or illusion) are, in Wittgenstein's terms, logical pictures of facts; to convey our thoughts to others, we need to express them in sentences (combinations of words, generally seen as names by Wittgenstein), which can be perceived by the senses.

The world view and the philosophy of language contained in the *Tractatus* have radical consequences: if language only has meaning when it pictures reality, then the statements of logic and mathematics (which deal with how language works/should work) have no 'meaning' (one cannot make a picture of how a picture represents reality), and so the propositions of the *Tractatus* itself are devoid of meaning, senseless (*sinnlos*). However, Wittgenstein recognized the importance, or usefulness, of these propositions: they serve as 'elucidations,' enabling us to make the distinction between what has meaning and what does not. Wittgenstein even stressed the importance of a 'mystical' dimension concerning our life, our religious beliefs, our ethical convictions, our aesthetic experiences; the crucial point for Wittgenstein is that this mystical dimension should not be presented as 'facts' (we deal here with 'problems of life'). Sentences that try to express this dimension are nonsensical (*unsinnig*): they do not picture facts, nor do they try to make explicit the way our language works. To say that the world exists is nonsensical, since its existence is not a fact in the world. But it shows itself, viz. in the existence of language. Language, indeed, is the totality of meaningful, i.e., fact-picturing sentences, and thus the limits of our language are the limits of our world. But when all has been said that can be said, we have not even touched upon the problems of life: they belong to the realm (the most important realm!) of the nonsensical, of what cannot be said but only shows itself.

Wittgenstein's views on meaning were endorsed by the members of the *Wiener Kreis* (Vienna Circle, the birthplace of neopositivism) – although Wittgenstein felt that nobody, not even Russell, had understood and grasped the contents and the (deeper, ethical) meaning of the *Tractatus*, and although the picture-theory was not adopted by the *Kreis*. The book was

submitted in June 1929 as a Ph.D. dissertation at Cambridge, where Wittgenstein had returned after World War I and a few wandering years (in 1920 he was a gardener in Klosterneuberg, between 1920 and 1926 he was a schoolteacher in the Austrian villages of Trattenbach, Puchberg, and Otterthal, and after that he became again a gardener in the monastery of Hütteldorf). The years 1927 and 1928 were spent in Vienna, where he designed a mansion (which he wanted 'free from all decoration and marked by a severe exactitude in measure and proportion') for his sister Margarete, and had regular contacts with members of the *Wiener Kreis*, especially Moritz Schlick, Friedrich Waismann, and Herbert Feigl. But Wittgenstein's 'return' to philosophy seems to have been caused by a lecture given in Vienna in March 1928 by L. Brouwer on the foundations of mathematics. Brouwer's theory of intuitionism in mathematics strongly appealed to Wittgenstein, who realized that mathematics is essentially a constructive activity, and that meaning lies in the recovery of the process of construction (of a proof, of a theorem, etc.), and not in the discovery of a (*a priori*) given truth. Wittgenstein's *Tractatus* already contained a number of statements about mathematics as a method (and not as a doctrine) and about the importance of 'making clear' what is meant (= elucidation), and presented a method (viz. truth tables) for calculating the truth or falsity of a proposition that is a truth-function of other propositions, but the picture-theory of meaning and the view of language as being essentially a nomenclature (a set of names) – both central ideas of the book – were of course hardly compatible with intuitionism and constructivism. It would take Wittgenstein several years to rebuild his philosophy, and to develop a completely new (and very original) theory of meaning. This new theory constituted the core of the philosophy of the 'later Wittgenstein,' as distinct from the 'younger Wittgenstein,' author of the *Tractatus*. Whether there is a radical break or a gradual transition between the two periods is a matter of dispute among Wittgenstein scholars, with some defending the discontinuity thesis and others the continuity view; a somewhat subversive, though not inaccurate, way to reconcile both views is to say that Wittgenstein remained interested in the ideas expounded in the *Tractatus*, but (mainly) in order to show how wrong they were.

The philosophy of the 'later Wittgenstein' was elaborated at Cambridge, where Wittgenstein started to lecture in January 1930, and where he had contact with Russell, G. E. Moore, and F. P. Ramsey. Wittgenstein taught there between 1930 and 1936, then spent one year living as a solitary in Norway, and returned to Cambridge in 1937, where he later succeeded Moore in the chair of philosophy. During World War II, Wittgenstein, by then a British citizen (since 1938), took the side of the allied troops and worked at Guy's Hospital in London and subsequently in the Royal Victoria Infirmary in Newcastle. He resumed his teaching at Cambridge in 1944, but took an early retirement in 1947. He went to live in Ireland and then spent some time in the United States. In late 1949 he was diagnosed with cancer, and from that time on he prepared himself for his death. He lived briefly in Vienna and in Oxford, then went to Norway, before spending the last months of his life in Cambridge, in the home of his physician. He died on April 29, 1951, leaving behind a mass of unpublished materials (notebooks, lecture notes, unfinished book manuscripts, letters), much of which was published (and translated) by his students and friends after his death.

Wittgenstein's Cambridge years were marked by intense philosophical activity, by a considerable amount of academic teaching, and by the shift from a dogmatic and axiomatic formulation (so typical of the *Tractatus*) to a dialogue form of philosophizing, with more questions raised than answers given. The later Wittgenstein also covered a wide variety of topics, and most prominently beyond the domains of logic and mathematics (although in the years 1937–1944 he wrote down his remarks on the foundations of mathematics): he reflected upon (ordinary) language, psychology, ethics, aesthetics, and religion, and dealt with the general problems of meaning, knowledge, belief, and social behavior. During the first years after his return to Cambridge, Wittgenstein was particularly interested in verification as the (constructivist) method of establishing the meaning of propositions (in the *Tractatus* he had not dealt with the role of verification); but as soon as the early 1930s he realized that the demand of verification should not be kept too strict, and that there is also meaning beyond (or behind) what can be verified. Wittgenstein completely abandoned the picture-theory and the concept of meaning as an (ideal) object, i.e., precisely those principles in virtue of which he could be seen as an adherent of neopositivism or of logical atomism; most of his work from the 1930s and 1940s can be seen as a criticism of the views of the *Wiener Kreis* and of Russell's philosophy (in his conversations with Schlick and Waismann of the years 1929–1932, the differences separating Wittgenstein from the *Wiener Kreis* are clearly expressed). From the early 1930s on, when he wrote the manuscript of his *Philosophical grammar* (the first part of which deals with 'meaning,' 'rules,' and 'language use') and dictated the

contents of *The blue and brown books*, Wittgenstein stressed the manifold forms, functions, and uses of language. The best-known work from the later Wittgenstein's philosophical legacy, to which most often reference is made, is the *Philosophical investigations* (written, with an interruption in 1945–1947, between 1936 and 1949; this text, one of the most finished among Wittgenstein's manuscripts, was posthumously published in 1953). The philosophy – or the philosophical itinerary – formulated in this (not very systematically structured) book implies a dynamic view of language, seen not as a collection of names but as a toolkit containing 'countless' kinds of uses of words and sentences and a changing set of 'language-games' (*Sprachspiele*), such as describing, reporting, guessing, translating, thanking, greeting, and telling jokes (the 'language-games' were previously dealt with in *The blue book*). The essential question to ask then is not 'What is the meaning of sentence S?,' but 'How is S used here?' and 'How does S fit within a larger set of sentences?' Asking these questions is inquiring after the meaning of activities, and only in this way are we able to get a view of the 'grammar rules' of each game. The answer (or multiple answers) to these questions also require(s) that we consider sentences (and the words contained in them) in their 'surroundings' (in Wittgenstein's terminology). Here we see the basic difference from the doctrine of the *Tractatus*: meaning is not shown by the sentence taken on itself, but it becomes (partly) manifest in each of the uses to which a sentence is put; also, whereas in the *Tractatus* Wittgenstein held that any proposition presupposes all other propositions (because of their 'common essence'), in his later work he emphasizes the idea that we only hit upon segments of the whole of language. A very elliptical summary of the later Wittgenstein's theory of meaning is therefore 'Meaning *is* use' (use/employment/application; the German terms are *Gebrauch*/*Verwendung*/*Anwendung*). The implications of this dynamic and 'perspectivist' view on meaning have been drawn by Wittgenstein's commentators, who have been assembling, comparing, and confronting the dispersed remarks, questions, and musings – on meaning, knowledge, belief, and (especially in the second part of the *Philosophical investigations*) emotion, sensation, remembering – found in the posthumously published materials, in view of the fact that Wittgenstein abstained from giving definitions of the key terms in his later philosophy. The 'language-games' that can be performed in using language show intricate relationships and partly overlapping, partly diverging features (in their formal aspects, their functions, their purposes): Wittgenstein spoke of 'family resemblances,' which justify the general designation 'language-game' without implying an 'essential' unity (language functions in multiple ways); the same vague conception applies to the structure of language, which Wittgenstein saw as irregularly patterned (the structure of language is compared to the plan of an old town, with irregular streets and squares, dead alleys, etc.).

The later Wittgenstein proposed a philosophy that is basically an activity of constant questioning, doubting, observing, and relativizing; it is a message of caution against doctrinarism, (hasty) generalization, speculation, one-sided approaches, and also 'bewitchment' (by language, by so-called evidence, by theories): the aim is 'to show the fly the way out of the fly-bottle' (overgeneralization and one-sidedness lead us into the bottle). It is therefore characterized by a search to determine criteria (or at least one good criterion) in order to find out something about states of the mind (belief, thought, will, hope, etc.) while avoiding the recourse to introspection (in his *Remarks on the foundations of mathematics* Wittgenstein stressed the foundational role of mathematical operations). To understand the 'grammar rules' of the language-games, it is necessary to observe the uses of sentences that function within the various games, and this requires contextual and interpersonal observation: we cannot make abstraction of the 'surroundings' in which words and sentences are used, and language-games (and thus also language) are a social reality, i.e., language-games are (integrated as) *forms of life* (the relationship between language and experience figures prominently in Wittgenstein's *Remarks on colour*). Wittgenstein denied the possibility of 'private rules' and therefore of a private language: rules functioning within a game are necessarily shared rules (they exist only because there is agreement about them), and therefore there are no rules that would be followed by only one individual, since following a rule consists in 'doing the same.' The issue of private rules, in connection with linguistic behavior and linguistic competence, has become a main topic of post-Wittgensteinian debate between scholars holding an empiricist view of language and those holding a rationalist, innatist view of language; Wittgenstein himself rejected both flat behaviorism and unqualified mentalism, because of their one-sidedness and being out of touch with linguistic reality. The ultimate argument for such a view lies of course in a person's (linguistic) history: we have acquired language by learning how sentences are used in what types of contexts (the language games are part of 'our natural history,' as Wittgenstein put it).

In the two main phases of his philosophical career Wittgenstein exerted great influence upon

contemporary philosophical conceptions: whereas his *Tractatus* was a source of inspiration for neopositivists (although Wittgenstein's 'deeper' message was radically opposed to the doctrine of logical positivism, as well as to Russell's logical atomism), his later work inspired British analytical philosophers (although the later Wittgenstein's method was not so much one of analysis, but rather one of questioning and of patiently describing, i.e., of recovering the 'uses-in-context'). A similar twofold impact on linguistic work can be observed: whereas the doctrine of the *Tractatus* has inspired work on the categorical structure of language as being, ideally, a nomenclature with syntactic rules for combining names (thus justifying a monolithic type of analysis), the ideas put forward in the *Philosophical investigations* (and in the other writings of the 1930s and 1940s) have inspired scholars favoring a pragmaticist view of meaning and an ethnographic study of language (thus justifying a multifunctional and combinatory or polythetic approach, integrating meaning, knowledge, and action; Wittgenstein's *On certainty* offers a nice illustration of such an approach). Beyond that, Wittgenstein's life and works, also when misunderstood or indirectly known, have inspired psychologists (Wittgenstein lectured on 'philosophical psychology,' especially on the 'body-mind problem,' and had written important *Remarks on the philosophy of psychology*), anthropologists, educationists, moralists, and artists.

Wodak, Ruth (b. 1950)

D Hanauer, Indiana University of Pennsylvania, Indiana, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

Ruth Wodak has made significant contributions to the theoretical, methodological, and empirical study of discourse. Her initial training was as a sociolinguist and in her early work she combined text linguistics, sociolinguistics, and discourse analysis in both the legal and the clinical frameworks. Her early books, *The language of defendants at court* (1975) and *Language behavior in therapy groups* (1986), exemplify this approach. Her book *Disorders of discourse* (1996) offers a significant summary of her initial positions on discourse analysis.

Wodak's work is mainly situated within the context of Critical Discourse Analysis (CDA) and sociolinguistics. This approach is based on the underlying assumption that power is both distributed and reflected through discourse. Accordingly, the analysis of the written and spoken texts that occupy the everyday world provides information concerning the power relations that are present within any given social discoursal context. CDA is particularly concerned with resisting power relations that reproduce inequality and generate oppression. This is achieved through the elucidation of those discoursal practices that justify, initiate, and maintain the ideology and ultimately the power of the dominant elite. CDA has the critical aim of empowering individuals and groups who have been marginalized within the power structures of society by making them aware of inclusive and excluding discursive practices.

Wodak has contributed to CDA on several different levels. On the theoretical and methodological levels, her books and articles have developed theories of text planning, argumentation, and comprehension as well as a series of both qualitative and quantitative methods of analysis. The emphasis on theoretically informed methods of analysis has been a hallmark of this body of writing and has allowed CDA to emerge as a systematic and replicable approach to textual analysis. This work is exemplified through her books *Methods of text and discourse analysis* (St. Titscher *et al*., 2000) and *Critical discourse analysis: theory and interdisciplinarity* (Wodak and Weiss, 2003) as well as through her continuing role as editor of the journal *Critical Discourse Studies*. Wodak's specific approach to CDA has been termed the discourse-historical approach.

On the empirical level, Wodak has utilized her theoretical and methodological approach to CDA to explore social inequalities. On the broadest level, her empirical research has addressed the relationship between language and politics. In this work, she has provided analyses of political discourse particularly in relation to national and transnational identities. Within this context, the issues of minority languages, multilingualism, and intercultural communication have been addressed. Her books *The discursive construction of national identity* (Wodak *et al*., 1999), *The costs of multilingualism* (Wodak *et al*., 2003), and *The Haider phenomenon* (Wodak and Pelinka, 2002) and her continued editorship of the *Journal of Language & Politics* represent this aspect of her empirical work.

Wodak's work on racism, prejudice, and discrimination may be the clearest example of the empirical application of CDA to the continued marginalization of specific social groups. In this context, Wodak has

Ruth Wodak has made significant contributions to the theoretical, methodological, and empirical study of discourse. Her initial training was as a sociolinguist and in her early work she combined text linguistics, sociolinguistics, and discourse analysis in both the legal and the clinical frameworks. Her early books, *The language of defendants at court* (1975) and *Language behavior in therapy groups* (1986), exemplify this approach. Her book *Disorders of discourse* (1996) offers a significant summary of her initial positions on discourse analysis.

Wodak's work is mainly situated within the context of Critical Discourse Analysis (CDA) and sociolinguistics. This approach is based on the underlying assumption that power is both distributed and reflected through discourse. Accordingly, the analysis of the written and spoken texts that occupy the everyday world provides information concerning the power relations that are present within any given social discoursal context. CDA is particularly concerned with resisting power relations that reproduce inequality and generate oppression. This is achieved through the elucidation of those discoursal practices that justify, initiate, and maintain the ideology and ultimately the power of the dominant elite. CDA has the critical aim of empowering individuals and groups who have been marginalized within the power structures of society by making them aware of inclusive and excluding discursive practices.

Wodak has contributed to CDA on several different levels. On the theoretical and methodological levels, her books and articles have developed theories of text planning, argumentation, and comprehension as well as a series of both qualitative and quantitative methods of analysis. The emphasis on theoretically informed methods of analysis has been a hallmark of this body of writing and has allowed CDA to emerge as a systematic and replicable approach to textual analysis. This work is exemplified through her books *Methods of text and discourse analysis* (St. Titscher *et al*., 2000) and *Critical discourse analysis: theory and interdisciplinarity* (Wodak and Weiss, 2003) as well as through her continuing role as editor of the journal *Critical Discourse Studies*. Wodak's specific approach to CDA has been termed the discourse-historical approach.

On the empirical level, Wodak has utilized her theoretical and methodological approach to CDA to explore social inequalities. On the broadest level, her empirical research has addressed the relationship between language and politics. In this work, she has provided analyses of political discourse particularly in relation to national and transnational identities. Within this context, the issues of minority languages, multilingualism, and intercultural communication have been addressed. Her books *The discursive construction of national identity* (Wodak *et al*., 1999), *The costs of multilingualism* (Wodak *et al*., 2003), and *The Haider phenomenon* (Wodak and Pelinka, 2002) and her continued editorship of the *Journal of Language & Politics* represent this aspect of her empirical work.

Wodak's work on racism, prejudice, and discrimination may be the clearest example of the empirical application of CDA to the continued marginalization of specific social groups. In this context, Wodak has

made significant contributions to the understanding of the discoursal construction of stereotypes and propagation of discrimination in public and private spheres. Of particular importance is the presence of an extensive analysis system that when applied to spoken and written texts clearly demarks the linguistic realization of racist orientations, positions, and statements. The development of this analysis system specific to the linguistic manifestation of prejudice and discrimination has allowed Wodak and other researchers to illuminate the presence of racism in contemporary social discussions as well as the historical presence of this phenomenon. Her books *The semiotics of racism: approaches in critical discourse analysis* (Reisigl and Wodak, 2001), *Racism at the top* (Wodak and van Dijk, 2000), and *Discourse and discrimination: rhetoric of racism and anti-Semitism* (Wodak and Reisigl, 2001) are examples of this body of research.

Wodak has also applied the empirical tools of CDA to the issue of gender in society. In broad terms, her work has explored the discursive practices of female socialization. This research has addressed the way men and women interact in conversation, the communication of women in different personal and institutional settings, and the representation of women in media discourses. In addition to exploring gender in society, Wodak has also provided guidelines for nondiscriminatory language use. Her books *Gender and discourse* (Wodak, 1997) and *Communicating gender in context* (Kotthoff and Wodak, 1997) demonstrate her application of CDA to gender research.

Wodak's research interests also include issues of organizational discourse. In this context, she has applied discoursal analyses to the doctor–patient relationship and the discoursal practices of international European organizations. This work has explored decision-making processes and addresses the social ramifications of these decisions. Her book *EU discourses on unemployment: an interdisciplinary approach to employment, policy making and organizational change* (Wodak *et al.*, 2000) exemplifies this body of research.

Wodak's contribution to linguistic science has been recognized through several awards and prizes. In 1996, she was awarded the Wittgenstein Prize for Elite Researchers, which allowed her to conduct 6 years of continuous interdisciplinary team research. In 1997, she was elected as a corresponding member of the Philosophic-Historical Class of the Austrian Academy of Sciences. In 2001, she was awarded the Scientific Prize of the City of Vienna, and in 2003 she was awarded the Verkauf–Verlon Prize for Anti-Fascist Research and Writing.

Ruth Wodak is currently Professor of Discourse Studies at Lancaster University. She moved from the University of Vienna, Austria, where she was full professor of applied linguistics since 1991. She is director of the Centre 'Discourse-Politics-Identity,' located at the University of Vienna, and codirector of the Austrian National Focal Point of the European Monitoring Centre for Racism, Xenophobia and Anti-Semitism.

Wolaitta

A Amha, University of Leiden, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The term 'Wolaitta' (Wolaytta) designates both the speakers and the language discussed in this article. Their administrative unit, known as the Wolaitta Zone, is part of the Southern Peoples, Nations and Nationalities Regional State of Ethiopia. The northern neighbors of the Wolaitta are the Kambatta (Kambaata) and Hadiyya (Cushitic); the southern neighbors are the Gamo and Gofa peoples (Omotic). The western and eastern parts of Wolaitta are bounded by the Omo and Bilate rivers, respectively. Most of the Wolaitta are farmers. According to the 1994 national census of Ethiopia, there are 1 210 000 Wolaitta speakers. For the names of closely related languages, see the language family tree in Figure 1.

The Sound System

Consonants

Table 1 lists a consonant inventory of Wolaitta. [p] and [Φ] are free variants in word-initial and intervocalic positions; [Φ] does not occur as a geminate or as a member of a consonant cluster. The labial implosive is attested both in word-initial and medial positions, as in *ɓánk'a* 'very sour' and *šoɓɓá* 'armpit,' and the alveolar implosive occurs only in word medial position, as in. *šóɗɗe* 'frog.' [ž] is used marginally and only in ideophonic words. Gemination is contrastive.

Vowels

Wolaitta has a five-vowel system with each vowel having a longer counterpart (Table 2). Examples are *mára* 'calf,' *maára* 'row' and *boóra* 'ox,' *bóra* 'critic.'

Figure 1 Omotic family tree, based on Fleming (1976).

Table 1 Consonant inventory

	l			
	r			
w		y		

Table 2 Vowel inventory

i, ii		u, uu
e, ee		o, oo
	a, aa	

Syllable Structure

CV, CVV, CVC, and CVVC syllable types are attested, as in *tá* 'I', *ʔéé* 'yes,' *mal.dó* 'sorghum,' and *keet.tá* 'house' (where the period indicates the syllable break). As the syllabification of the words *maldó* and *keettá* demonstrates, geminates and consonant clusters are split between two different syllables; also, clusters and geminates consist of only two members and they occur only word-medially. Syllable nucleus may be simple or branching.

Tone-Accent

Wolaitta is a tone-accent language. The language has two tones (high and low) used for making lexical distinction, as in *góda* 'lord, chief' versus *godá* 'wall' (where high tone is marked with ´ and low tone is not marked). With a few exceptions (e.g., *ha* 'this,' *ta* 'my'), there are no words with just low tones; instead, lexical items have at least one high tone, mainly occurring on the ultimate or penultimate vowel. There are, however, a few numerals and nouns with ante-penultimate high tone, for example, *másunta* 'wound' and *k'éretta* 'split wood,' which seem to be historically derived from complex forms.

Nouns

Basic nouns in Wolaitta end in one of the following vowels: [e], [o], or [a] (Table 3). Which of these vowels a particular word may take cannot be predicted. There are no nouns ending in [i] or [u] in Wolaitta, although such nouns are attested in related languages.

Table 3 Basic nouns

[e]-ending		*[o]-ending*		*[a]-ending*	
búhe	'dust'	káwo	'dinner'	šaáfa	'river'
molé	'fish'	šooró	'neighbor'	keettá	'house'

Table 4 Plural marking

Singular	*Nominative plural*	*Accusative plural*	*Gloss*
šaáfa	šaáfa-t-i	šaáfa-t-a	'river'
šooró	šooro-t-í	'šooro-t-á'	'neighbor'

Plural Marking

On definite nouns, plural is marked by the morpheme *-t-*; indefinite nouns are not marked for plurality. Singular is unmarked. Examples are in Table 4.

Case, Gender, and Definiteness

Case, gender, and definiteness are designated cumulatively by portmanteau morphemes. In animate nouns, gender is determined by sex. Inanimate nouns are generally inflected like masculine nouns; but, when a diminutive meaning is intended, they may be inflected as feminine nouns. Plural nouns take the same nominative and accusative case markers as masculine singular nouns. Examples are in Table 5.

The genitive case is marked by *-ee* in definite feminine nouns and by *-u* in plural nouns. In masculine nouns, the genitive and accusative cases are formally identical. The possessor noun always precedes the possessed noun. Consider the forms of *šooró* 'neighbor' and *gošší* 'farm' in (1).

(1a)	šooró	gošša	'a neighbor's farm'
(1b)	šoor-úwa	gošša	'the neighbor's (MASC) farm'
(1c)	šoor-eé	gošša	'the neighbor's (FEM) farm'
(1d)	šooro-t-ú	gošša	'the neighbors' farm'

Peripheral/semantic cases such as instrumental (*-ra*), ablative (*-ppe*), dative (*yo/-ssi*), and so on are attached to a noun already marked with the genitive (for feminine and plural nouns) or accusative (for masculine singular nouns). Compare the examples in (1) with those in Table 6.

Nominal Derivation

There are several productive derivational suffixes, for example, *-ta* in *laggé-ta* 'friendship' (*lágge* 'friend') and *-tétta* in *zoʔó-tétta* 'redness' (*zoʔó*

Table 5 Definiteness, case, and gender inflection

	Basic noun	*Definite masculine singular*		*Definite feminine singular*		*Definite plural*	
		NOM	*ACC*	*NOM*	*ACC*	*NOM*	*ACC*
/a/-	keettá 'house'	keettáy	keettáa	keettíya	keettíyo	keetta-t-í	keetta-t-a
ending	naʔá 'child'	naʔáy	naʔáa	naʔíya	naʔíyo		
/o/-	migído 'ring'	migídoy	migíduwa	migídiya	migídiyo	migído-t-i	migído-t-á
ending	šooró 'neighbor'	šooróy	šoorúwa	šooríya	šooríyo	šooro-t-í	šooro-t-á
/e/-	šóďďe 'frog'	šóďďee	šóďďiya	šóďďiya	šóďďiyo	zeére-t-i	zeére-t-á
ending	zeére 'orphan'	zeéree	zeériya	zeériya	zeériyo		

Table 6 Peripheral semantic cases

	'from a'		*'with a'*	
	Indefinite	*Definite*	*Indefinite*	*Definite*
Singular	šooró-ppe 'from a neighbor (MASC/FEM)'	šoor-úwa-ppe 'from the neighbor (MASC)'	šooró-ra 'with a neighbor (MASC/FEM)'	šoor-úwa-ra 'with the neighbor (MASC)'
		šoor-eé-ppe 'from the neighbor (FEM)'		šoor-eé-ra 'with the neighbor (FEM)'
Plural		šooro-t-ú-ppe 'from the neighbors'		šooro-t-uú-ra 'with the neighbors'

Table 7 Derivational suffixes

Noun	*Agent nominal*	*Adjective*
kiíta 'message'	kiit-ánca 'messenger'	
ʔóla'a 'fight/war'	ʔol-ánca 'fighter'	
dooná 'mouth'		doon-aáma 'talkative'
wolk'á 'power'		wolk'-aáma 'one with power'

'red'). Suffixing *-ancạ* to a noun may derive agent nouns; whereas suffixing *-aáma* to a noun derives an adjective (Table 7).

Adjectives and Adverbs

Adjectives end in one of the word-final vowels, *e*, *o*, or *a*. When used as modifiers, adjectives are not marked for gender, case, or number; they generally do not show agreement with the head noun. However, when the head noun is dropped, the adjective must be marked for these categories.

(2a) keéha 'kind'
(2b) keéha šooro-y 'the kind neighbor (NOM)'
(2c) keéha-y 'the kind one'

In the inchoative, the adjectival base is affixed with tense-aspect and mood markers, as in:

(3a) keeh-iísi 'he became kind'
(3b) keeh-aásu 'she became kind'
(3c) keeh-íbénna 'he did not become kind'

Manner adverbs are mainly derived by suffixing the locative marker *-n*, the instrumental *-ra*, or the ablative *-ppe* to nominals. For example:

(4a) ʔakeéka-ni ʔoott-á
attention-LOC do-2.SING.IMP
'work carefully!'
(4b) keeh-í-ppe harg-eési
be_kind-í-ABL be_sick-3.MASC.SING.IMPERF
'he is extremely/badly sick'
(4c) ʔiss-í-ppe y-iite
one-í-ABL come-2.PL.IMP
'come together!'

Lexical time-adverbs include *haʔʔí* 'now,' *kasé* 'earlier,' *háčči* 'today,' and *wontó* 'tomorrow.'

Pronouns

The basic pronoun paradigms of Wolaitta are possessive, nominative, and accusative. Dative, ablative, and locative pronouns are formed by adding the

Table 8 Pronouns

Person[a]	*Possessive*	*Nominative*	*Accusative*	*Dative*	*Ablative*
1 SING	ta	táání/tá	táná	taássí	taáppé
2 SING	ne	néení/né	nená	neéssí	neéppé
3 FEM SING	ʔi	ʔá	ʔó	ʔíssí	ʔíppé
3 MASC SING	ʔa	ʔí	ʔá	ʔássí	ʔáppé
1 PL	nu	núúní/nú	núná	nuússi	nuúppé
2 PL	ʔinte	ʔínté	ʔíntena	ʔíntéssí	ʔíntéppé
3 PL	ʔeta	ʔetí	ʔetá	ʔetássi	ʔetáppé
3 SING LOG	ba	—	báná	baássi	baáppe
3 PL LOG	banta	—	bántana	bántassi	bántappe

[a]LOG, logophoric form.

respective case suffixes (i.e., *-ssi*, *-ppe* and *-n*(*i*), as in the nouns) to the accusative/possessive ones (see Table 8). Note the gender syncretism between third-person singular pronouns in the forms in Table 8. The pronoun sets with *ba*(-) are used when the subject of the sentence is coreferential with an object or possessive noun in the same sentence, as shown in (5a), which contrasts with the noncoreferential form in (5b).

(5a) ʔí ba šoor-úwa
3.MASC.SING.SUBJ 3.LOG neighbor-MASC.ACC
maadd-eési
help.3.MASC.SING.IMPERF
'he$_x$ helps his$_x$ neighbor'

(5b) ʔí ʔa
3.MASC.SING.SUBJ 3.MASC.SING.POSS
šoor-úwa maadd-eési
neighbor-MASC.ACC help-3.MASC.SINGIMPERF
'he$_x$ helps his$_y$ neighbor'

In the logophoric form (LOG), the gender distinction in the third-person singular form is neutralized.

Verbs

Subject Agreement, Aspect, Negation, and Modality

In affirmative declarative sentences, a three-way temporal distinction is made, for example, *beʔ-iísi* 'he saw,' *beʔ-eési* 'he sees,' *beʔ-aná* 'he/she/I (etc.) will see.' The verb shows subject agreement; object agreement is not marked on the verb (see Tables 9 and 10).

Future tense/aspect is formed by suffixing an invariable *-ána* to a verb root:

(6) kúnd-aná 'I/you/he/she/we/you (PL)/ they will see'

In negative declarative sentences, there is only two-way distinction, between perfective negative (Table 11) and imperfective negative (Table 12); the present and future forms are reduced to one

Table 9 Perfective paradigm

Singular	*Plural*
kúnd-aási 'I fell'	kúnd-ída 'we fell'
kúnd-ádasa 'you fell'	kúnd-ídeta 'you (PL) fell'
kúnd-iísi 'he fell'	kúnd-ídosona 'they fell'
kúnd-aásu 'she fell'	

Table 10 Present tense paradigm

Singular	*Plural*
kúnd-aísi 'I fall'	kúnd-oósi 'we fall'
kúnd-aása 'you fall'	kúnd-eéta 'you (PL) fall'
kúnd-eési 'he falls'	kúnd-oósona 'they fall'
kúnd-aúsu 'she falls'	

Table 11 Perfective negative

Singular	*Plural*
beʔ-á-beíkke 'I did not see'	beʔ-í-boókko 'we did not see'
beʔ-á-baákká 'you did not see'	beʔ-í-beékkétá 'you (PL) did not see'
beʔ-í-beénná 'he did not see'	beʔ-í-boókkóná 'they did not see'
beʔ-á-beíkkú 'she did not see'	

Table 12 Imperfective negative

Singular	*Plural*
beʔ-íkke 'I do/will not see'	beʔ-ókko 'we do/will not see'
beʔ-ákka 'you do/will not see'	beʔ-ékketa 'you (PL) do/will not see'
beʔ-énna 'he does/will not see'	beʔ-ókkona 'they do/will not see'
beʔ-úkku 'she does/will not see'	

Table 13 Verbal inflection in interrogative sentences

Interrogatives			
Person	*Perfective*	*Imperfective Pres/Hab.*	*Future*
1 SING	beʔ-ádina 'did I see?'	beʔ-aína	beʔ-ané
2 SING	beʔ-ádi 'did you see?'	beʔ-áy	beʔ-uúte
3 MASC SING	beʔ-íde 'did he see?'	beʔ-í	beʔ-ané
3 FEM SING	beʔ-áde 'did she see?'	beʔ-áy	beʔ-ané
1 PL	beʔ-ído 'did we see?'	beʔ-íyo	beʔ-ané
2 PL	beʔ-ídeti 'did you (PL) see?'	beʔ-eéti	beʔ-uúteti
3 PL	beʔ-ídona 'did they see?'	'beʔ-íyona'	beʔ-ané

Table 14 Imperative

Singular	*Plural*	*Gloss*
demm-á	demm-ité	'find!'
y-á	y-iité	'come!'

paradigm: *beʔ-énna* 'he does/will not see' and *beʔ-íbénna* 'he did not see.'

Interrogatives

There are the following content question words in Wolaitta: *ʔaí* 'what,' *ʔai-gé* 'which (MASC),' *ʔai-nná* 'which (FEM),' *ʔaí-ssi* 'why,' *ʔa-udé* 'when,' *ʔá-wan* 'where,' and *ʔoóni* 'who.'

Both in content-question-word and polar-interrogative clauses, the verb inflects for subject, tense/aspect, and modality (i.e., [+question]). The actual subject-agreement- and tense/aspect-marking morphemes are distinct from that observed for declarative sentences. Examples are shown in Table 13.

Imperative and Optative Moods

Second-person singular and plural imperatives are marked by *-á* and *-(i)ité*, respectively (Table 14). The optative/hortative involves only the third-person singular and plural forms. It is marked by *-ó* for third-person singular masculine and by *-ú* for feminine. For third-person plural, it is marked by *-óna*.

(7a) demm-ó 'let him find'
(7b) demm-ú 'let her find'
(7c) demm-óna 'let them find'

The imperative and optative/hortative forms take the same negative marker, *-ópp-/úpp-*, which is formally distinct from the negation-marking morpheme in affirmative declarative sentences.

(8a) demm-ópp-a 'don't find (2.SING)!'
(8b) demm-ópp-ite 'don't find (2.PL)!'

Table 15 Verb root extensions

Verb root	*Causative stem*	*Passive/ reciprocal*	*Intensive/ repetitive*	*Gloss*
k'ant'-	k'ant'-is(s)-	k'ant'-étt-	k'ant'-erett-	'cut'
bóg-	bóg-is(s)	bóg-étt-	bog-erett-	'plunder'

(9a) demm-ópp-ó 'let him not find!'
(9b) demm-úpp-ú 'let her not find!'
(9c) demm-ópp-óná 'let them not find'

Verb root extension in Wolaitta includes causative, passive, reciprocal, reflexive, and intensive verbs (Table 15).

Clauses

Simple Declarative Clauses

The most frequently used word order is SOV. However, S may occur immediately before V when it is in contrastive focus. Also, subject and object may be omitted.

(10) ʔasa-t-í méhe-t-a
person-PL-MASC.NOM cattle-PL-MASC.ABS
baiz-ídosona
sell-3.PL.PERF
'the people sold the cattle'

In phrases, modifiers precede the head. Demonstratives generally precede numerals and adjectives when both modify the same noun. Example (11a) is an NP with adjectives and a demonstrative; (11b) is a sentence containing an NP with a relative clause.

(11a) ha heezzú guútta naa-t-í
this three small child-PL-MASC.NOM
'these three small children'

(11b) maay-úwa meec'c'-íya
cloth-MASC.ACC wash-IMPERF.REL
naʔ-iya daapur-aásu
child.FEM.NOM be_tired-3.FEM.SING.PERF
'the girl who is washing clothes is tired'

Complex Clauses

In complex sentences, adverbial and complement clauses precede main clauses. Clausal linking is indicated by various verbal affixes attached to the dependent clause. Examples (12a) and (12b) are simultaneous, examples (12c) and (12d) are anterior and examples (12e) is conditional. Simultaneous and anterior morphemes further indicate whether the subject of the dependent clause is the same as that of the main clause.

(12a) ?attúma ?asa-t-í keettaa
male person-PL-NOM house.MASC.ACC
keet't'-íšin mác'c'a ?asa-t-í
build-DS.SIMUL female person-PL-NOM

Wolf, Friedrich August (1759–1824)

D Haug, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

As the prodigious son of a church organist, the German classical philologist Friedrich August Wolf began his studies in 1777 at the University of Göttingen, at that time the leading German university in the field of classical philology.

According to a widespread but ultimately false belief, Wolf was the first in Germany to enroll as *studiosus philologiae* (student of philology) and to be accepted as that in spite of resistance from the leaders of the university. Though legendary, the story illustrates well Wolf's seminal role in creating and defining the independent discipline of classical philology as it was to be practiced in the universities of the 19th and early 20th centuries.

After his studies, and a brief period as a pedagogue, Wolf was appointed to a chair at the University of Halle in 1783, where he remained until the university was forced to close after Prussia's defeat in 1806. He

As the prodigious son of a church organist, the German classical philologist Friedrich August Wolf began his studies in 1777 at the University of Göttingen, at that time the leading German university in the field of classical philology.

According to a widespread but ultimately false belief, Wolf was the first in Germany to enroll as *studiosus philologiae* (student of philology) and to be accepted as that in spite of resistance from the leaders of the university. Though legendary, the story illustrates well Wolf's seminal role in creating and defining the independent discipline of classical philology as it was to be practiced in the universities of the 19th and early 20th centuries.

After his studies, and a brief period as a pedagogue, Wolf was appointed to a chair at the University of Halle in 1783, where he remained until the university was forced to close after Prussia's defeat in 1806. He

then went to Berlin and served as a professor at the newly founded university there until his death in August 1824.

Wolf is today mostly remembered for his *Prolegomena ad Homerum*, published in 1795, in which he claimed that the Homeric poems had been composed without the aid of writing, and that the texts as we have them are substantially the product of Alexandrian criticism at least half a millennium after the time of the poet. Today we can see that this thesis was less ground-breaking than was commonly held before, since similar views were held by Wolf's teacher Heyne, and the method employed owes much to Johann Gottfried Eichhorn's (1752–1827) *Einleitung in das Alte Testament*, published 1780–1783. Nevertheless, the book played an important role in posing the Homeric question, the treatment of which would later serve as a career vehicle for many a young, aspiring classical scholar.

Arguably, Wolf was even more influential through his lectures on *Alterthumswissenschaft* ('science of antiquity'), which reached a large audience and were later published by his pupils Hoffmann (1833) and Stockmann (1831). Wolf stressed the unity of the field, including history, mythology, literary criticism, rhetoric, and archaeology, but always put special emphasis on linguistics, both on the particular grammar of Greek and Latin and on general, philosophical grammar (cf. Gürtler, 1810) in the tradition of Sanctius, Port-Royal, and Condillac, but with influences from Herder's organicism. 'Philosophical grammar' was later strongly opposed by scholars of the emerging comparative Indo-European studies that would soon become hegemonic in linguistics. For all his emphasis on linguistics in philology, Wolf may have contributed to the ensuing gulf between classical philology and linguistics later deplored by Georg Curtius. His insistence on restricting classical philology to the languages of *Gebildete Völker* had the same effect: though intended to set philology free from theology and Hebrew philology, it no doubt hampered classical scholars' interest in comparative studies throughout the 19th century.

Wolfram, Walt (b. 1941)

M Newman, Queens College/City University of New York, Flushing, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Walt Wolfram's route to becoming a pioneer and leading figure in variationist sociolinguistics might be considered as 'nonstandard' as many dialects he analyzed. Wolfram was born in 1941, the son of working-class German immigrants. As a youth, he knew no one who had attended college, and he is the only one in his family to do so. He probably would not have gone himself were it not for an athletic scholarship to Wheaton College, an evangelical institution in Illinois. He recalls being as involved in football and basketball as in academics, incidentally providing him with athletic skills that would later prove useful in fieldwork with teenage respondents. More important, it was during these studies – his major was anthropology and his minor Greek – that he realized he 'had a mind' and a desire to use it. The religious nature of the college is also significant for his future trajectory because his desire to be a missionary led him to linguistics. This began at the University of Chicago and continued at the Summer Institute of Linguistics and later the Hartford Seminary Foundation, where he received his M.A. and Ph.D. in 1969. His turn to a career in academics was the result of "'diverted' faith and finances." Wolfram is hardly a missionary linguist, but there is undeniably certain carryover from that initial impulse throughout his later career.

For instance, although Wolfram has been president of the Southeastern Conference on Linguistics (1998–1999), the American Dialect Society (1997–1999), and the Linguistics Society of America (2001–2002), his service is not limited to high-profile positions. He

then went to Berlin and served as a professor at the newly founded university there until his death in August 1824.

Wolf is today mostly remembered for his *Prolegomena ad Homerum*, published in 1795, in which he claimed that the Homeric poems had been composed without the aid of writing, and that the texts as we have them are substantially the product of Alexandrian criticism at least half a millennium after the time of the poet. Today we can see that this thesis was less ground-breaking than was commonly held before, since similar views were held by Wolf's teacher Heyne, and the method employed owes much to Johann Gottfried Eichhorn's (1752–1827) *Einleitung in das Alte Testament*, published 1780–1783. Nevertheless, the book played an important role in posing the Homeric question, the treatment of which would later serve as a career vehicle for many a young, aspiring classical scholar.

Arguably, Wolf was even more influential through his lectures on *Alterthumswissenschaft* ('science of antiquity'), which reached a large audience and were later published by his pupils Hoffmann (1833) and Stockmann (1831). Wolf stressed the unity of the field, including history, mythology, literary criticism, rhetoric, and archaeology, but always put special emphasis on linguistics, both on the particular grammar of Greek and Latin and on general, philosophical grammar (cf. Gürtler, 1810) in the tradition of Sanctius, Port-Royal, and Condillac, but with influences from Herder's organicism. 'Philosophical grammar' was later strongly opposed by scholars of the emerging comparative Indo-European studies that would soon become hegemonic in linguistics. For all his emphasis on linguistics in philology, Wolf may have contributed to the ensuing gulf between classical philology and linguistics later deplored by Georg Curtius. His insistence on restricting classical philology to the languages of *Gebildete Völker* had the same effect: though intended to set philology free from theology and Hebrew philology, it no doubt hampered classical scholars' interest in comparative studies throughout the 19th century.

Walt Wolfram's route to becoming a pioneer and leading figure in variationist sociolinguistics might be considered as 'nonstandard' as many dialects he analyzed. Wolfram was born in 1941, the son of working-class German immigrants. As a youth, he knew no one who had attended college, and he is the only one in his family to do so. He probably would not have gone himself were it not for an athletic scholarship to Wheaton College, an evangelical institution in Illinois. He recalls being as involved in football and basketball as in academics, incidentally providing him with athletic skills that would later prove useful in fieldwork with teenage respondents. More important, it was during these studies – his major was anthropology and his minor Greek – that he realized he 'had a mind' and a desire to use it. The religious nature of the college is also significant for his future trajectory because his desire to be a missionary led him to linguistics. This began at the University of Chicago and continued at the Summer Institute of Linguistics and later the Hartford Seminary Foundation, where he received his M.A. and Ph.D. in 1969. His turn to a career in academics was the result of "'diverted' faith and finances." Wolfram is hardly a missionary linguist, but there is undeniably certain carryover from that initial impulse throughout his later career.

For instance, although Wolfram has been president of the Southeastern Conference on Linguistics (1998–1999), the American Dialect Society (1997–1999), and the Linguistics Society of America (2001–2002), his service is not limited to high-profile positions. He

has made contributions that are less likely to garner academic prestige, such as the promotion of sociolinguistically informed practice in language education and speech pathology and support for public appreciation of dialect diversity. This participation involved a long association with the nonprofit Center for Applied Linguistics (CAL) in Washington, DC, from 1967 to 1992. Less formally, he has consulted for communication disorders therapists, and he developed and even taught linguistics-oriented curricula for eighth-graders (13- and 14-year-olds). In addition, he is author or coauthor of numerous booklets for professional communities and the general public (Dannenberg and Wolfram, 1999; Wolfram, n.d.). He participated in the classic 1987 American Tongues video documentary and in the North Carolina Language and Life series, which was shown on public television throughout the state. In a similar vein, he coauthored the first major introductory text dedicated to the study of American English dialects (Wolfram and Schilling-Estes, 1998), and he has appeared as a guest on numerous talk shows on television and radio.

Wolfram's research has two prongs. One involves the quintessentially American sociolinguistic phenomenon of racial dialects, a fascinating linguistic phenomenon but one inevitably bound up with the problem of continued racial and social divisions. No one in sociolinguistics has studied more of these varieties, including Native American English (Wolfram *et al.*, 2002), Asian American English (Wolfram *et al.*, 1986), and two varieties of Latino English (Wolfram, 1974; Wolfram *et al.*, 2004). His work on African American English (AAE) includes the first monograph on that dialect (Wolfram, 1969) and explorations of varieties spoken by African Americans in isolated communities. This later work finds evidence for a more complex development of early AAE than had been previously assumed, providing insights into the dispute between the Anglicist and Creolist hypotheses on AAE origins. The roles of early modern British vernaculars, emphasized by Anglicists, and creolization processes, emphasized by Creolists, may really be seen as complementary, not mutually exclusive. Specifically, what we now know as AAE is the result of the blending of a variety of different forms of early African American Englishes influenced variably by these two sources (Wolfram, 2003).

The other thrust of Wolfram's work involves Southern European American English varieties, a focus undoubtedly related to the location of his academic positions. These began in Washington, DC, with his appointment as research associate in 1967 at CAL, where he moved on to become senior researcher in 1970, research director in 1980, and finally distinguished scholar in 1992. In 1970, he also obtained a faculty position at the University of the District of Columbia, where he remained until 1992. That year, he moved to his current position as William C. Friday Distinguished Professor at North Carolina State University in Raleigh.

Wolfram's research has largely, though not exclusively, focused on North Carolina ever since. His best known work in this area involves the English spoken in Hyde County on the North Carolina coast, particularly the Ocracoke Brogue – spoken on the eponymous barrier island (Wolfram and Schilling-Estes, 1995). The salient phonological feature of this dialect involves the raising of the nuclei in the diphthongs /ay/ and /aw/, leading to the stereotype expression 'It's hoi toide on the seund soide' ([ɪts hɔɪ tɔɪd ɑn ðə sɛʊn sɔɪd]) and so the nickname of speakers as 'Hoi Toiders.' Yet, although this dialect is a much commented on part of local identity, it is also in 'ebb tide,' and much research interest lies in the social and linguistic phenomena associated with its decline (Wolfram and Schilling Estes, 1995). A noteworthy finding involves the role of social structure and social identity mediated by small groups – most famously in a group of poker players – in inhibiting or advancing linguistic change. This work anticipates the emphasis on the role of small group dynamics as the vehicle of transmission of larger linguistic ideologies and norms that have recently become prominent in the field (Eckert, 2000).

Language variation suffers from the paradox of being a topic of endless fascination to many nonlinguists and yet, at the same time, the source of much misunderstanding and even discrimination. Wolfram's work in both deepening our understanding of the social and linguistic significance of variation and in expanding the general knowledge of this topic makes him a model of the potential of what those of us who work in the variationist paradigm can do.

Wolof

F Mc Laughlin, University of Florida, Gainesville, FL, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Wolof is a member of the northern branch of the Atlantic family of Niger-Congo languages, formerly known as West Atlantic, and is spoken primarily in Senegal as well as in parts of Gambia and Mauritania on the West African coast. In Senegal, Wolof serves as a lingua franca, and is spoken by upwards of 80% of the population as either a first or second language, making for a total of no fewer than 6–7 million speakers and quite possibly more. Wolof society has traditionally been hierarchically stratified (Diop, 1981) and is composed of two main social groups, *ñeeño* and *géer*. The former group consists of endogamous artisans or castes, including griots (verbal artists), blacksmiths, leatherworkers, and musicians; the latter group is composed of noncasted people and nobles. Today, a majority of Wolof speakers are Sufi Muslims, most having converted to Islam en masse in the late 19th and early 20th centuries.

Genetic Affiliation

Sapir (1971) hypothesized that Wolof, along with Serer-Sine and Pulaar or Fula, belongs to the Senegal subgroup of northern Atlantic languages. Although the three languages are clearly related, Serer-Sine and Pulaar resemble each other much more closely than either of them do Wolof. Until much more historical work is done on the northern Senegal languages, the exact relationship of Wolof to these languages, as well as to other Atlantic languages, and especially to the Cangin languages spoken around the Senegalese city of Thiès, will remain unresolved.

Phonetics and Phonology

Like most Niger-Congo languages (Clements, 2000), the consonantal inventory of Wolof, given in **Table 1** in standard Wolof orthography, distinguishes four main places of articulation: labial, alveolar, palatal, and velar. Voiced and voiceless stops, voiced prenasalized stops, voiceless fricatives, and simple nasal stops occur in the four places of articulation. Voiceless prenasalized stops no longer occur word-initially, but historical records and some place-names, such as Mpal, provide evidence that they once did. The have now been replaced by simple voiceless stops. There is also a voiceless uvular stop in the language, as in the words *sàq* 'granary' and *bëqët* 'to be cowardly.' There is a tap [r] and a lateral [l] in addition to two glides, the labiovelar [w], and the palatal [j]. Consonant length is distinctive in Wolof: compare *dag* 'valet' to *dagg* 'to cut,' and *jaw* 'to cook for a long time' to

[+ATR]		[−ATR]	
i	u		
é	ó	e	o
ë		a	

Figure 1 The Wolof eight-vowel system; vowels have either a plus or minus value for the advanced tongue root (ATR).

jaww 'sky'; however, not all consonants have a geminate counterpart, notably the prenasalized stops, the fricatives, and the alveolar tap. Geminate forms of the latter, however, occur in ideophones, as in *jérr* 'of being hot' and *curr* 'of being red.' Notable in the northern Atlantic context is the absence of implosive stops in Wolof. Wolof has an eight-vowel system in which vowels have either a plus or minus value for the advanced tongue root (ATR) feature. The [+ATR] vowels comprise the set i, u, é, ó, and ë; the [−ATR] vowels are e, o, and a (**Figure 1**). All vowels are written in standard Wolof orthography, and the character ë represents schwa. The [+ATR] and [−ATR] vowels are phonemically distinct in Wolof stems, as evidenced by the pairs *reer* 'to dine' and *réer* 'to be lost,' and *woor* 'to fast' and *wóor* 'to be sure or trustworthy.' Nominal and verbal stems and a substantial number of derivational suffixes harmonize for the ATR feature. Regressive height harmony also exists in the language. Vowel length is distinctive in Wolof, as in the pairs *bax* 'to boil' and *baax* 'to be good' and *fit* 'to tie on' and *fiit* 'soul,' but the mid-central vowel ë does not have a long counterpart. Although most Niger-Congo languages are tonal, Wolof, like Serer-Sine and Pulaar, is not a tonal language. Intonational patterns are fairly flat according to Rialland and Robert (2001), and stress falls on the initial syllable of a word in Wolof.

Morphology and Syntax

Wolof has a noun class system comprising 10 classes, of which 8 are singular and 2 are plural, marked by a single consonant. Unusually, there is no morphological marking for class on the noun, but the classifier consonant appears on nominal determiners as in the following examples, in which the determiner follows the noun:

1. m-class: *picc mi* 'the bird,' *picc male* 'that bird.'
2. y-class: *picc yi* 'the birds,' *picc yale* 'those birds.'
3. k-class: *nit ki* 'the person,' *nit kale* 'that person.'
4. ñ-class: *nit ñi* 'the people,' *nit ñale* 'those people.'

Wolof has approximately 30 verbal extensions, inflectional and derivational affixes that encode a variety of concepts such as reciprocal, applicative, causative, locative, etc. The verb *gis* 'to see' has, among others, the following derivatives: *gis* 'to see,' *gisaat* 'to see again,' *gise, gisante* 'to see each other,' *gisandoo* 'to see together,' and *gisaale* 'to see ('while you're at it').' Verb-to-noun derivation may exhibit reduplication (*gis* 'to see,' *gis-gis* 'opinion'; *xam* 'to know,' *xam-xam* 'knowledge'), suffixation (*gudd* 'to be long,' *guddaay* 'length'), and consonant mutation (*baax* 'to be good,' *mbaax* 'goodness'; *sonn* 'to be tired,' *cono* 'fatigue'). It is arguable as to whether a distinct category of adjectives can be said to exist in Wolof, since adjectival forms can be subsumed under the category of verb (Creissels, 2000; Mc Laughlin, 2004). Although basic word order in Wolof is subject-verb-object, the information structure of Wolof is encoded in an elaborate focus system (Creissels and Robert, 1998). The minimal verb phrase consists of a bare verb plus an auxiliary that encodes person, number, and focus. Examples (1)–(4) show four different ways to say 'Ami saw the thief,' using neutral, subject, object, and verbal focus, respectively:

(1) Ami gis na sàcc ba.
Ami see 3S:PERF thief DET

(2) Ami moo gis sàcc ba.
Ami 3S:SFOC see thief DET

(3) Sàcc ba la Ami gis.
Thief DET 3S:OFOC Ami see

(4) Ami dafa gis sàcc ba.
Ami 3S:VFOC see thief DET

Urban Wolof

Urban Wolof, and especially that of the capital, Dakar, exhibits heavy lexical borrowing from French, as in Examples (5) and (6) (Mc Laughlin, 2001) (French loans are in boldface):

(5) **Feu** bi **rouge** na.
light DET be red 3S:PERF
'The traffic light turned red.'

(6) Dafa d-oon **errer** ci
3S:VFOC IMPERF-PAST wander PREP
monde bi rekk.
world DET just
'He was just wandering around the world.'

Introduction

There is a certain paradox connected with the concept 'word.' On the one hand, we often talk about 'words' in a way that presupposes that we know what a word is. For example, in the instructions to the authors contributing to this encyclopedia, it is stated that each article should have a maximal length of 10 000 words. Moreover, we do not have to be linguists to talk about words; in many languages a word that corresponds to the English *word* is part of the everyday vocabulary (but not in all – see Dixon and Aikhenvald, 2002). Nevertheless, defining the concept 'word' in precise linguistic terms is notoriously difficult. Not only is there the problem that there are several definitions that do not all converge on the same set of linguistic objects, but, in addition, some of the definitions are so vague or circular that they are of little use when it comes to picking out the words in a given sequence of speech.

Within the field of linguistics, the lack of precision of the term 'word' is to some degree acknowledged, and, consequently, more specific terms are often employed to convey its various meanings. Some of these specific terms have a clear definition, whereas others are still not precise enough to be of any help in delimiting a coherent class of elements.

Phonological Words

One clearly distinguishable meaning of the term 'word' is 'phonological word.' However, examples of phonological words that do not correspond to what we would intuitively take to be a word can be found in many (perhaps all) languages. The Turkish example in (1) and the Finnish example in (2) illustrate this.

(1) çáy evì
tea house
'tea house'

(2) pää-kaupunki
head-city
'capital'

Judging by the patterns of primary stress placement and of vowel harmony, which have the phonological word as their domain in the languages at hand, the strings given in (1) and (2) must consist of two phonological words. From a nonphonological point of view, we nevertheless take them to be compounds and, hence, single words.

Conversely, it is not unusual for an element with wordlike behavior in the syntax, that is, with independent syntactic distribution, to be a part of a

Introduction

There is a certain paradox connected with the concept 'word.' On the one hand, we often talk about 'words' in a way that presupposes that we know what a word is. For example, in the instructions to the authors contributing to this encyclopedia, it is stated that each article should have a maximal length of 10 000 words. Moreover, we do not have to be linguists to talk about words; in many languages a word that corresponds to the English *word* is part of the everyday vocabulary (but not in all – see Dixon and Aikhenvald, 2002). Nevertheless, defining the concept 'word' in precise linguistic terms is notoriously difficult. Not only is there the problem that there are several definitions that do not all converge on the same set of linguistic objects, but, in addition, some of the definitions are so vague or circular that they are of little use when it comes to picking out the words in a given sequence of speech.

Within the field of linguistics, the lack of precision of the term 'word' is to some degree acknowledged, and, consequently, more specific terms are often employed to convey its various meanings. Some of these specific terms have a clear definition, whereas others are still not precise enough to be of any help in delimiting a coherent class of elements.

Phonological Words

One clearly distinguishable meaning of the term 'word' is 'phonological word.' However, examples of phonological words that do not correspond to what we would intuitively take to be a word can be found in many (perhaps all) languages. The Turkish example in (1) and the Finnish example in (2) illustrate this.

(1) çáy evì
tea house
'tea house'

(2) pää-kaupunki
head-city
'capital'

Judging by the patterns of primary stress placement and of vowel harmony, which have the phonological word as their domain in the languages at hand, the strings given in (1) and (2) must consist of two phonological words. From a nonphonological point of view, we nevertheless take them to be compounds and, hence, single words.

Conversely, it is not unusual for an element with wordlike behavior in the syntax, that is, with independent syntactic distribution, to be a part of a

phonological word. For example, the English sentence *I'll come* consists of two phonological words, *I'll* and *come*, but we presumably do not want to say that *I'll* is just one word outside of the phonology. Instead, we say that '*ll* is a short form of *will*, which clearly has its own representation in the syntax. But so has the pronoun *I*. Hence, *I'll* is a phonological word consisting of two syntactic elements.

More examples with the same characteristics are presented in Selkirk and Shen (1990). Selkirk and Shen claimed that in Shanghai Chinese (Wu Chinese), functional elements form a phonological word with a preceding lexical element. (In this context, 'lexical element' means 'a member of one of the major categories N, A, and V.') The basis of this claim is the observation that sequences made up of a lexical item and one or more following function words are treated as one phonological word with respect to tone. This is exemplified in (3), in which the extension of each phonological word is indicated by brackets.

(3a) ['mo ku 'noN 'va]
scold ASP 2.SING Q
'has someone scolded you?'

(3b) [tsou taw] ([noetsiN]
walk to Nanjing
'walk to Nanjing'

(3c) [taN 'ngu] ['njitsz]
hit 1.SING son
'hit my son'

We see that the phonological words here do not necessarily correspond to syntactic constituents. For example, in (3c) the possessor '*ngu* 'my' belongs syntactically with the noun '*njitsz* 'son,' whereas phonologically it goes with the verb.

In sum, Selkirk and Shen's treatment of phonological words in Shanghai Chinese shows that, in this language, items with an independent syntactic realization are routinely combined into phonological words. This is arguably a very common phenomenon crosslinguistically; in any language that has small but wordlike functional elements, these elements will not constitute separate phonological words in normal continuous speech. Hence, if a string of linguistic elements can be identified as a phonological word, it cannot be concluded from this fact that the same string is also a word in any nonphonological sense.

Lexemes and Lexical Words

Another meaning of the term 'word' is 'lexeme'; that is, the word seen as an entry in the speaker's mental lexicon. However, in the case of words that take inflection, each lexical entry subsumes at least some inflected forms. For example, in English the lexical entry for CHILD must contain or point to the plural form *children* as well as the singular form *child*. Hence, the lexeme is not identical to the word as it occurs in actual language use. Moreover, it is a matter of controversy whether or not the lexical entry must include *all* relevant inflected forms. To illustrate, there is good reason to assume that the North Sami (North Saami) word forms *beana* 'dog (NOM)'and *beatnaga* 'dog (ACC)' are both listed as belonging to the lexeme BEANA 'dog,' but it is less clear whether *beatnagiiddisetguin* 'with their (own) dogs' is listed or produced online as we speak or write. But regardless of whether or not it is listed, the string is recognized as a word in a certain sense.

The relation between words and lexical entries is further complicated by the fact that the property of being listed may be ascribed to affixes, to words, to phrases, and even to sentences, so that some listed items are arguably smaller than what we normally take to be words, whereas others are considerably bigger. In (4) some examples are given of multiword collocations that are part of the mental lexicon of many speakers of English and that therefore can be referred to as lexical words.

(4a) do-it-yourself
(4b) black and white film
(4c) take *x* to the cleaners
(4d) how do you do?

The set of lexical words thus crosscuts the sets of grammatical units, from affixes to sentences. (For a more detailed discussion of the contents of the lexicon, see, for example, Di Sciullo and Williams, 1987; Jackendoff, 1997). Lexical words can also be distinguished from lexemes because nonce words are lexemes but arguably are not listed. Consequently, the notions 'lexeme' and 'lexical word' can both be left aside as special meanings of the term 'word.'

Grammatical Words

We have now identified three very different meanings of the term 'word': the phonological word, the lexeme, and the lexical word. These meanings have clear definitions, and in most cases it is relatively easy to determine which linguistic objects they apply to. Still, there is a very strong intuition among linguists and many nonlinguists alike that 'word' has yet another meaning that is not captured by any of the terms mentioned. This meaning has to do with the word as an entity that is located between morphemes and phrases in the structural hierarchy – that is, with what we may refer to as the 'grammatical word.' Moreover, it is often felt that this is the core meaning of the term 'word,' because it has to do with

the role that the word plays in the morphology and in the syntax.

Using the term 'grammatical word' to denote the nonphonological and nonlexical meaning of 'word' is not strictly correct because phonology is, of course, also a part of grammar. The expression 'grammatical word' is nevertheless commonly used in this sense in the linguistic literature and, for lack of a better term, this practice is followed here.

The grammatical word, then, appears to be what those without linguistic training associate with the term 'word.' As pointed out by Sapir (1921) and by numerous researchers after him, the grammatical word is psychologically real in many languages. The exception appears to be certain languages with grammatical markers that are preposed to their associated roots, where the markers in question can be seen as prefixes or as unbound particles (see, e.g., Julien, 2002). Apart from these cases, not only is the existence of words firmly established in speakers' minds, it is also usually clear which morpheme sequences are words and which are not. That is, in numerous languages the grammatical words are readily identified by ordinary speakers as well as by linguists.

On Criteria for Wordhood

Although many speakers have an intuitive idea of what constitutes a grammatical word in their language, it is not so easy to come up with a universal definition of the concept. Most attempts at doing so list a collocation of properties that are claimed to be typical of words, but, at the same time, these definitions tend to beg the question of what a word really is. For example, the grammatical word is often taken to be the unit that morphological operations, such as inflection, apply to and the linguistic entity that phrases and clauses are built from in the syntax. But, unfortunately, defining words as the domain of morphology is necessarily circular because 'morphological material' must mean whatever appears inside words, and the claim that words are the minimal building blocks of syntax is taken as an axiom in some theories, although it has been challenged by others. Thus, criteria such as these do not tell us what it is that leads us, linguists and nonlinguists, to identify certain strings as words in the first place.

This problem is brought into full light if we try to use the criteria just mentioned to determine the status of elements that may or may not be separate words. Consider the Mandarin Chinese examples shown in (5) (from Zheng, 1994) and (6) (from Norman, 1988).

(5) wo du le zhe ben shu
I read PERF this CLF book
'I have read this book'

(6) wo kan-le neibenr shu
I read-PERF that book
'I read that book'

In Mandarin Chinese, the perfective aspect marker *le* appears in postverbal position. In some works on Chinese, it is written as a separate word, as in (5). In other works, it is written as a suffix on the verb, as in (6). This suggests that the authors have different views on the word status of the aspect marker. If we now wanted to settle the question of whether the aspect marker belongs to the verbal word or not, how should we proceed?

It appears that the criteria for wordhood previously given are of little help in this matter because they only apply after the decision has been made. If the combination of verb and aspect marker is seen as one word, the idea that the word is the domain of morphology leads to the conclusion that the positioning of the aspect marker relative to the verb is determined by morphological principles. If, on the other hand, the aspect marker is seen as an independent grammatical word, its position must be determined by the syntax. Similarly, if verb plus aspect marker is one word, the claim that words are syntactic primitives forces us to see this word as an indivisible syntactic element. If the aspect marker is seen instead as a separate word, it must be allowed to have its own syntactic representation. Hence, regardless of whether it is true that morphological phenomena have relevance only inside the word and that words enter the syntax as indivisible wholes, this does not tell us whether or not the perfective marker in Mandarin Chinese is a part of the verbal word.

Trivial as this may seem, this illustrates the point that we need criteria for wordhood that are independent of our theory of how morphology and syntax work and interact and independent of our ideas of how words ought to behave. Instead of listing the properties that are ascribed to words by this or that theory, we ought to look for criteria that can serve as a reliable guide to the identification of words in any given string of speech.

Distributional Criteria

When speakers of a given language are able to recognize certain morpheme sequences as words in the grammatical sense, this ability indicates that they have access to a set of criteria that pick out the relevant morpheme sequences. The criteria most likely have to do with the distribution of these sequences. That is, wordhood is primarily determined by the criteria that were formulated by the structuralist linguists of the early 20th century.

One such criterion was given by Bloomfield (1933), who stated that a word is a free form that does not consist entirely of (two or more) lesser free forms; that is, a word is a 'minimal free form,' the smallest unit that may appear in isolation.

More precisely, an expression that can stand alone as an utterance is normally no smaller than a word – only in metalinguistic discourse can elements that are parts of words appear as utterances. However, many languages have elements that cannot appear in isolation but that are nevertheless seen as words. These elements have a purely grammatical content, and they are often small phonologically. Bloomfield himself noted the problem they pose for the minimal-free-form criterion. An example is the English article *the*, which is felt to be a word even though it is rarely spoken in isolation. Bloomfield pointed out that *the* has the same distribution as the elements *this* and *that*, which are fully acceptable as utterances. The examples in (7) serve as an illustration.

(7a) this linguist ~ this famous linguist
(7b) that linguist ~ that famous linguist
(7c) the linguist ~ the famous linguist

Because of the parallelism between *the,* on the one hand, and *this* and *that,* on the other, Bloomfield concludes that *the* should also be classified as a word. More generally, it appears that an element is a word if it can be replaced by something that is a word. We refer to this criterion as the substitution criterion.

Another criterion bearing on the present problem is found in Boas (1911/1969), where it is suggested that (relative) freedom of position, or independent distribution, is a necessary part of the definition of the word. Boas was thus willing to grant the status of word even to elements that cannot appear in isolation, given that their position relative to other elements of the clause is not entirely fixed.

If we apply the independent distribution criterion to *the*, we see from (7c) that *the* can appear immediately in front of the noun. But if an adjective is present, it will intervene between *the* and the noun. It is thus clear that the article *the* is not affixed to the noun any more than the demonstratives *this* and *that* are. Moreover, because *the* is normally the initial element of the nominal phrase that it belongs to, it will be preceded by whatever precedes the nominal phrase as a whole. Hence, the article *the* is not in a fixed position relative to any other element in the clause, and, consequently, it is regarded as a word.

We can now go back to the Mandarin Chinese aspect marker presented in (5) and (6) and look at it in the light of the criteria we have just discussed. It can be shown that this marker is always strictly adjacent to the verb and that it can never appear in isolation, although the verb can – for example, in answers to questions, as in (8b). The aspect marker must minimally be accompanied by a verb to make an utterance, as in (9b) (from Li and Thompson, 1981).

(8a) ni lai ma
2.SING come Q
'are you coming?'
(8b) lai
come
'yes'

(9a) júzi huài le ma
orange spoiled PFV Q
'are the oranges spoiled?'
(9b) huài le
spoiled PERF
'yes'

The complex consisting of a verb and an aspect marker has relatively free position within the clause. It can, for example precede the subject, as (10a), or follow both the subject and an adverbial, as in (10b) (both examples from Li and Thompson, 1981).

(10a) jin-lai-le yi-ge ren
enter-come-PERF one-CLF person
'a person came in'
(10b) wo zai nali zhu-le liang-ge yue
I at there live-PERF two-CLF month
'I lived there for 2 months'

Hence, on the minimal-free-form criterion and on the independent distribution criterion the Chinese perfective marker is not a word. Instead, it forms a word with the verb that it is adjacent to. As for the substitution criterion, it is of limited relevance here because an aspect marker can only be replaced by another aspect marker.

The preceding paragraphs were aimed at drawing the demarcation line between bound forms and words. To complete the discussion of wordhood, it is also necessary to look at the difference between words and phrases. Again, we turn to Bloomfield (1933), who observed that, in addition to the ability to occur in isolation and/or be substituted for elements that have this ability (and in addition to independent distribution, which he does not mention), there is another criterion for wordhood, namely indivisibility or internal cohesion, which distinguishes phrases from compounds and phrasal words. More precisely, even if both words and phrases can be built from words, with phrases it is normally the case that they can be broken up by additional words and phrases, whereas words that consist of words cannot be interrupted in this way. This is shown by the contrast between the phrase in (11) and the

compound in (12) and between the phrase in (13) and the phrasal word in (14).

(11a) a black bird
(11b) a black and beautiful bird

(12a) a blackbird
(12b) *a black-and-beautiful-bird

(13a) a jack in the box
(13b) a jack in the little box

(14a) a jack-in-the-box
(14b) *a jack-in-the-little-box

Compounds and phrasal words are thus examples of words that are not minimal free forms. The reasons for counting them as words is that they share with words the internal cohesion previously demonstrated and they also show the syntactic behavior of noncompound words. To borrow another example from Bloomfield, as a phrase *devil-may-care* would be a combination of a subject and two verbs, but as a word it is an adjective with the syntactic distribution of ordinary adjectives, as illustrated in (15).

(15) a devil-may-care taxi driver

These considerations have relevance for a case discussed by Boas (1911/1969). In Pawnee, a nominal free form, such as the one shown in (16a), can combine with a string that is normally taken to be a verb, for example, the string shown in (16b), in such a way that the nominal intervenes between the elements that make up the verb, as in (16c).

(16a) rīks
'arrow'
(16b) tā-t-u-kut
INDIC-1.SING-BEN-cut
'I have cut it for you'
(16c) tā-t-u-rīks-kut
INDIC-1.SING-BEN-arrow-cut
'I have cut your arrow'

This is an example of noun incorporation, the process that has caused so much debate over the years. What we have in (16c) is a combination of two potentially free forms, in which, moreover, one of them interrupts the other. On a strict interpretation of the criteria of minimality and internal cohesion, (16c) must therefore be a phrase. However, Boas noted that, regardless of its internal structure, this string behaves like an ordinary verb of the language. It is inflected like a verb and it has the distribution of a verb. He was therefore inclined to consider it a verb, which seems like a reasonable conclusion.

Let us now summarize what we have found to be the characteristics of the grammatical word. First, two properties that distinguish grammatical words from smaller elements are the ability to occur in isolation and the independent distribution within the phrase or the clause. If a string of one or more morphemes has either of these properties, it is minimally a grammatical word. Further, a grammatical word cannot be freely interrupted by other free forms. A string that can be interrupted by words or phrases is a phrase, unless there are very specific restrictions on the inserted material and the resulting complex behaves as a word on other relevant tests. Of these criteria, the necessary and crucial ones appear to be independent distribution and internal cohesion because forms that meet these two criteria tend to be regarded as words whether or not they are minimal free forms.

Borderline Cases: Clitics

There exists, however, a class of elements that are not so easily classified as words or as nonwords. These elements are clitics. An example of a clitic is the Greenlandic (Greenlandic Inuktitut) coordinator *-lu*, which is shown in (17) (from Fortescue, 1984).

(17a) ippasaq tikip-put aqagu-lu
yesterday arrive-INDIC.3.PL tomorrow-and
ikinnguta-at tiki-ssa-pput
friends-3.PL arrive-FU-INDIC.3PL
'they arrived yesterday and their friends will arrive tomorrow'
(17b) isir-puq ingil-lu-ni-lu
come.in-INDIC.3.SING sit.down-CTMP-4.SING-and
'she came in and sat down'
(17c) pilirtuttumik irrui-vuq ini-mi-nul-lu
quickly wash.up-INDIC.3.SING room-REFL-ALL-and
majuar-lu-ni.
go.up-CTMP-4.SING
'he washed up quickly and went up to his room'

According to the minimal-free-form criterion, *-lu* is clearly not a word. As for the independent distribution criterion, we see that *-lu* attaches to an adverb in (17a), to a verb in (17b), and to a noun in (17c). Its position is thus free in the sense that it is not defined relatively to any other element of the clause, such as subject or verb. But it is fixed in the sense that *-lu* always follows the first constituent of the second conjunct, whatever constituent this may be. In other words, *-lu* is a second-position clitic, which is a well-known type of special clitic (see, e.g., Klavans, 1985; Zwicky, 1985; Anderson, 1992).

In itself, the property of being a second-position clitic is not an indication of whether or not the element in question is a word. Notably, such idiosyncratic distribution is also found with elements that are wordlike phonologically and that are presumably regarded as words (see Anderson, 1992).

If we, instead, try applying the substitution test to *-lu*, it does not really lead to any clarification. It appears that *-lu* can only be replaced by other clitics with a similar coordinating function, as in the following examples (from Fortescue, 1984).

(18a) illu-at kusanar-puq kial-lu-ni-lu.
house-3.PL be.pretty-INDIC. 3.SING be.warm-CTMP-4.SING-and
'their house is pretty and (it is) warm'

(18b) qimmiq taanna nakuarsu-vuq saamasuu-llu-ni-li
dog that be.strong-INDIC.3SING be.gentle-CTMP-4.SING-but
'that dog is strong but (it is) gentle'

(19a) palasi niuirtur-lu
priest shopkeeper-and
'the priest and the shopkeeper'

(19b) palasi niuirtur-luunniit
priest shopkeeper-or
'the priest or the shopkeeper'

Hence, the question of whether clitics are words or not does not have a definite answer. It is not even clear that the question is relevant. Clitics are like words in some senses but are different in other senses. It seems that we must conclude, with Boas (1911/1969: 32), that "it seems entirely arbitrary whether these phonetic groups [the clitics] are considered as separate words." The important fact about clitics is that they are treated as independent elements by syntax and at the same time they are prosodically deficient. Whether we want to count such elements as (grammatical) words or not is ultimately a matter of taste.

The Referential Opacity of Words

In addition to the properties already mentioned, words are often claimed to have the semantic property of being referentially opaque (see, e.g., Di Sciullo and Williams, 1987; Spencer, 1991). To take Spencer's example, the element *tea* in *teapot* cannot subsequently be referred to by a pronoun, as shown in (20).

(20) *he took the tea$_i$pot and poured it$_i$ into the cup

It appears, however, that the opacity illustrated here is typical of languages with limited word-building resources and does not hold universally. In a highly synthetic language such as Greenlandic, for example, it is perfectly natural for the reference of an incorporated noun, as 'airplane' in (21a), to be picked up by agreement suffixes (or by empty pronominals) in a following clause, as in (21b) (examples from Sadock, 1980).

(21a) Suulut timmisartu-lior-poq
Søren.ABS airplane-make-INDIC.3.SING
'Søren made an airplane'

(21b) sulu-usa-qar-poq aquute-qar-llu-ni-lu.
wing-like-have-INDIC.3.SING rudder-have-CTMP-4.SING-and
'it has wings and a rudder'

In short, this sequence of sentences shows that in Greenlandic "an incorporated object establishes a discourse referent just as well as an independent indefinite NP" (Sadock, 1980: 311).

The referential opacity of English words is discussed by Sproat (1985, 1988), who argued that the reason we cannot generally refer anaphorically to an element that is contained within a word is that only maximal projections can have a reference. In English, coreference between an anaphor and an element inside a word is disfavored because elements inside words are not maximal projections. However, Sproat also noted that it is possible to violate the requirement that both members of an anaphoric relation must be maximal projections, so that patterns such as (22a) are marginally acceptable.

(22a) McCarthy$_i$ites are now puzzled by him$_i$
(22b) *he$_i$ distrusts McCarthy$_i$ites

The anaphoric islandhood of English words is thus not absolute. Further, (22a) can be compared to the completely ungrammatical (22b), in which the indicated coreference violates the Condition C of the Binding Theory. It appears that when parts of words are allowed to refer, they are subject to the same conditions that restrict coreference between ordinary syntactic elements – in other words, word-internal elements are in this respect treated by the syntax in the same way as full word categories.

The contrast between compounds in languages such as English, on the one hand, and complex words in languages with regular noun incorporation, on the other, was commented on by Baker (1988), who noted that, whereas in English N-V combinations surface as deverbal nominals (*truck-driver, man-watching*), in languages traditionally termed polysynthetic similar combinations regularly appear as main verbs, with a normal predicative function. The fact that elements inside those verbs can be fully referential was explained by Baker as a consequence of the syntactic nature of the word formation in question. That is, in a construction such as (21a) it is possible for the verbal word to have both a referential and a predicative function just because these functions are fulfilled by separate elements inside the word – elements that are separate syntactic heads at an earlier stage of the derivation.

It should be obvious from these considerations that referential opacity is not a reliable criterion for wordhood. It can be retained as such by denying constituents with internal referring elements the status of grammatical words, as Di Sciullo and Williams (1987: 107) in effect did when they maintained that, if an alleged word is composed of syntactically accessible parts, it is not a syntactic atom or a morphological object (which in their theory are the essential properties of syntactic and morphological words, respectively) but merely a phonological word. But, again, the argumentation is circular, saying that because a grammatical word contains no syntactically accessible parts, elements that do are not grammatical words. This is an example of what Sproat (1988) pointed out: once a hypothesis of lexical integrity is stipulated, it follows trivially that reference into a word is ruled out.

Final Remarks

To the extent that grammatical words can be unambiguously identified at all, the distributional criteria mentioned here will arguably suffice to identify the grammatical words in any string of speech. But, more important, from these criteria we cannot infer anything about the mechanisms of grammar that have formed the words. In particular, the view of grammatical words outlined here does not provide an answer to the question of whether words are formed in the lexicon (i.e., in a presyntactic component of grammar), whether words are formed in the syntax, or whether word-forming processes operate in both the lexicon and the syntax.

If grammatical words are characterized by their distributional properties, it is even possible that grammar involves no specifically word-forming processes at all. This is argued by Julien (2002), who stated that words are not so much formed as perceived. That is, whenever a sequence of morphemes shows independent distribution and internal cohesion, it will be seen as a word regardless of how the sequence came to have these properties. One possibility is that the sequence is one syntactic head; another possibility is that other constituents can move relative to the sequence in question. Hence, there need not be one particular syntactic configuration that corresponds to a grammatical word.

We might object to this that because we are often so confident about the word status of any given morpheme sequence, being a word must mean having some deep property that is the cause of the observable distributional properties. However, the psychological reality of words and the lack of awareness of word-internal morphemes on the part of linguistically naïve speakers need not be taken to mean that the elements that are commonly termed words form a homogeneous class in any theoretically interesting way. The psychological reality of words could be a consequence of their distributional properties; because words are the minimal morpheme strings that can be used as utterances and are also the minimal morpheme strings that may be permuted more or less freely, words are the minimal linguistic units that speakers consciously can manipulate. It is, then, no surprise that words are something that speakers are generally aware of. Word-internal morphemes, on the other hand, cannot be consciously manipulated the way words can, and, because of this, word-internal morphemes are less salient than words in the awareness of speakers.

Since the 1970s, the analysis of written text has played an increasingly important role in applied linguistics, for instance in areas such as education, the analysis of media texts, and, more recently, Internet communication and critical discourse analysis. Gradually it has become evident that it was no longer viable to focus only on the verbal aspects of such texts, not only because they use images as an integral part of the text but also because visual composition (layout), color, and typography play an increasingly important role in structuring them, through the use of space, typography (including special typographic signs such as bullet points), and color coding. As a result, linguistic or linguistically inspired methods for integrating the analysis of the linguistic and nonlinguistic aspects of written text have begun to emerge.

Paris School Structuralism

The first linguistically inspired approach to the analysis of images and image–text relations was that of 1960s Paris School structuralist semiotics.

Using media texts such as advertisements and news photographs as his data, Roland Barthes' (1977) work in this area focused on the concepts of 'denotation' and 'connotation.' In defining these concepts, he drew on the work of Hjelmslev, who had argued that different ways of expressing the same concept can have different meanings, if only because the same concept can be expressed in different languages, and speakers therefore never simply communicate a concept but communicate their country of origin as well. Extending Hjelmslev's approach to the analysis of images, Barthes proposed to analyze images in terms of two layers of meaning, denotation, the layer of 'what, or who, is represented here' and connotation, the layer of 'what ideas and values are expressed through what is represented, and through the way in which it is represented.' In other words, much as in John Stuart Mill's original use of the two terms, denotation was interpreted as reference to concrete people, places, and things, and connotation as reference to abstract concepts. Although this is often misunderstood, for Barthes, connotations were not subjective associations but "culturally accepted inducers of ideas" (1977: 23). In a key example (1973: 116), originally from 1959, he described an image on the cover of *Paris-Match* that showed a young black soldier saluting the French flag. The denotation is what is shown: 'a black soldier salutes the French flag.' The connotation is a more abstract concept, conveying a late colonialist ideology, "a purposeful mixture of Frenchness and militariness," as Barthes described it (1973: 116).

In a later essay, Barthes specified key signifiers of connotation: objects (e.g., the flag in the above example) and poses (e.g., the salute). There is, he wrote, an unwritten 'dictionary' of poses that "form ready-made elements of signification" (1977: 22). He added that connotation can also come about through the style of artwork or through techniques of photography such as "framing, distance, lighting, focus, speed": "An inventory needs to be made of these techniques, but only insofar as each of them has a corresponding signified of connotation sufficiently constant to allow its incorporation in a cultural lexicon of technical 'effects'" (1977: 23).

Barthes' approach to image–text relations focused on the concepts of 'anchorage' and 'relay.' In the case of 'anchorage,' words 'elucidate' pictures, selecting specific aspects from the meaning potential of the image: "[T]he text directs the reader through the signifieds of the image, causing him to avoid some and receive others" and "remote-controls him towards a meaning chosen in advance" (1977: 39). Since the 1970s, the analysis of written text has played an increasingly important role in applied linguistics, for instance in areas such as education, the analysis of media texts, and, more recently, Internet communication and critical discourse analysis. Gradually it has become evident that it was no longer viable to focus only on the verbal aspects of such texts, not only because they use images as an integral part of the text but also because visual composition (layout), color, and typography play an increasingly important role in structuring them, through the use of space, typography (including special typographic signs such as bullet points), and color coding. As a result, linguistic or linguistically inspired methods for integrating the analysis of the linguistic and nonlinguistic aspects of written text have begun to emerge.

Paris School Structuralism

The first linguistically inspired approach to the analysis of images and image–text relations was that of 1960s Paris School structuralist semiotics.

Using media texts such as advertisements and news photographs as his data, Roland Barthes' (1977) work in this area focused on the concepts of 'denotation' and 'connotation.' In defining these concepts, he drew on the work of Hjelmslev, who had argued that different ways of expressing the same concept can have different meanings, if only because the same concept can be expressed in different languages, and speakers therefore never simply communicate a concept but communicate their country of origin as well. Extending Hjelmslev's approach to the analysis of images, Barthes proposed to analyze images in terms of two layers of meaning, denotation, the layer of 'what, or who, is represented here' and connotation, the layer of 'what ideas and values are expressed through what is represented, and through the way in which it is represented.' In other words, much as in John Stuart Mill's original use of the two terms, denotation was interpreted as reference to concrete people, places, and things, and connotation as reference to abstract concepts. Although this is often misunderstood, for Barthes, connotations were not subjective associations but "culturally accepted inducers of ideas" (1977: 23). In a key example (1973: 116), originally from 1959, he described an image on the cover of *Paris-Match* that showed a young black soldier saluting the French flag. The denotation is what is shown: 'a black soldier salutes the French flag.' The connotation is a more abstract concept, conveying a late colonialist ideology, "a purposeful mixture of Frenchness and militariness," as Barthes described it (1973: 116).

In a later essay, Barthes specified key signifiers of connotation: objects (e.g., the flag in the above example) and poses (e.g., the salute). There is, he wrote, an unwritten 'dictionary' of poses that "form ready-made elements of signification" (1977: 22). He added that connotation can also come about through the style of artwork or through techniques of photography such as "framing, distance, lighting, focus, speed": "An inventory needs to be made of these techniques, but only insofar as each of them has a corresponding signified of connotation sufficiently constant to allow its incorporation in a cultural lexicon of technical 'effects'" (1977: 23).

Barthes' approach to image–text relations focused on the concepts of 'anchorage' and 'relay.' In the case of 'anchorage,' words 'elucidate' pictures, selecting specific aspects from the meaning potential of the image: "[T]he text directs the reader through the signifieds of the image, causing him to avoid some and receive others" and "remote-controls him towards a meaning chosen in advance" (1977: 39). In other

words, anchorage is a conjunctive relation of specification between word and image in which words specify the meaning of images that, in themselves, are 'polysemous,' open to a range of possible interpretations. In the case of 'relay,' "text and image stand in a complementary relationship." They are both "fragments of a more general syntagm" (1977: 41). As an example, he cites comic strips, in which pictures show the speaker(s) and the context, and words their speech. The two concepts are thus close to what Halliday (1994) calls 'elaboration' and 'extension,' except that 'elaboration' includes not just 'specification' but also a range of elaborative relations, including rephrasing, summarizing, exemplifying, and so on.

Barthes's concepts have been widely adopted in media studies. A well-known example of their application to political discourse is Stuart Hall's (1973) article 'The determination of news photographs,' which shows how captions can interpret relatively ambiguous shots of politicians according to newspapers' editorial policies.

Christian Metz, in his work of the 1960s, applied linguistic concepts to the study of film. Having initially attempted to find the filmic equivalents of phonological and syntactic form classes, he concluded that film shots are not "doubly articulated" and that the structure of film shots cannot be compared to the structure of sentences. Film shots simply reproduce what was in front of the camera, relaying the meanings of action, dress, and so on. Larger textual structures, however, can be studied in a linguistic spirit. In his most widely quoted paper of the period (1974) he outlined a 'syntagmatics' of film that was, in effect, a systematic overview of the conjunctive relations that can exist between the shots and scenes of a film, and that built on constructivist theories of editing by 1920s filmmakers and theorists such as Pudovkin, Eisenstein, and Timoshenko (cf. van Leeuwen, 1991). These conjunctive relations are for the most part temporal, although temporality in film involves more than simple sequentiality and includes simultaneity ('parallel editing'), flashbacks, and flash forwards. In addition, there are 'descriptive' syntagms, where a place is 'described,' not by showing it in a single shot, but through a scene showing a series of 'detail' shots, and comparative syntagms, in which shots with similar or contrasting content are edited together. This is a form of editing introduced by constructivist filmmakers to make specific political points, for example, by intercutting a scene showing workers with the slaughtering of a bull to depict the destruction of the spirit of the working class by capitalism. Metz's syntagmatics has been picked up again in linguistically inspired approaches to film (van Leeuwen, 1991; Iedema, 2001).

In the same period, Jacques Durand (1983) wrote an influential article presenting a structural classification of the rhetorical figures that had been described in the classical literature on rhetoric, and demonstrating that they can all be applied, not just to words, but also to images. His examples were taken from advertisements. Thus, a visual oxymoron might show a basket of strawberries in the snow, a visual chiasmus a picture of a father and a son wearing each other's clothes and carrying each other's newspapers, a visual metonymy a block of ice instead of a refrigerator (in an advertisement for refrigerators), and so on.

I have discussed only three examples here, but during the 1960s and early 1970s many other similar studies were published, mostly in the French journal *Communications*.

Although I will restrict myself here to approaches based on linguistics, the study of word and image has also played a vital role in iconography, a branch of art history occupying itself with representation and meaning in works of art. Although iconographers do not develop descriptions of 'visual languages' and focus on the work of individual artists, or on specific themes or schools, their work offers important clues for the study of word and image, especially where it concerns artworks based on mythological and Biblical texts (Schapiro, 1973 is an example; Van Leeuwen, 2001 discusses iconography in more detail).

Functional Linguistics

A more recent linguistically inspired approach to the study of word and image is strongly influenced by the functional linguistics of Michael Halliday (1978, 1994).

Kress and van Leeuwen (1996) base their approach on Halliday's three metafunctions (1978): the ideational function of constructing representations of the world; the interpersonal function of creating relations between the participants in acts of communication; and the textual function of marshalling individual representations-cum-interactions into coherent texts that can be recognized as types. They also follow Halliday in linking specific systems of visual grammar to specific metafunctions. While Barthes' approach had been 'lexical,' based on the denotative and connotative meanings of the individual people, places, objects, and poses depicted in images, Kress and van Leeuwen's approach is 'grammatical,' focusing on the way visual composition creates meaningful relations between the people, places, and things in images, not only on the broader textual level, but also within individual images or 'shots.'

According to Kress and van Leeuwen, the ideational function is visually realized by a grammar of

Figure 1 Execution (after Eddie Adams's photograph of 1968).

transitivity, which comprises two types of syntagm, the narrative and the conceptual. In narrative syntagms, the 'participants' are realized by 'volumes' and the 'processes' by 'vectors.' The formal terms ('volume' and 'vector') are derived from the art theorist Arnheim (1974), the functional terms ('participant' and 'process') from Halliday. In other words, word and image can realize the same semantic functions, but in different ways – in language, participants are typically realized by nominal groups, and processes by verbal groups.

To take an example, Eddie Adams's famous photograph of a summary execution on the streets of Saigon (Figure 1) contains two participants, Nguyen Ngoc Loan, the South Vietnamese officer who points the gun, and the Vietcong suspect who is about to die. The two participants are the main volumes, clearly demarcated against a somewhat out-of-focus background, and Loan's arm, holding the gun, forms a vector connecting the two. In this syntagm the two participants have different functional roles. The participant from whom the vector emanates (here Loan) is the Actor; the participant at whom the vector is directed (the Vietcong suspect) is the Goal (the terms are again taken from Halliday). As there are two participants, the syntagm is transitive. An intransitive action syntagm would contain only the Actor and the vector.

The same relationship can also be realized in diagrams. The participants are then boxes with words in them, or diagrammatic pictures, while the vector is realized by an arrow. Eye lines, which connect participants through the direction of the look of one of the participants, form a different kind of vector, and hence realize a different kind of process, a 'reaction' rather than an action. Reactions, too, can either be transitive or intransitive.

Conceptual syntagms realize a process, not through vectors, but through some kind of spatial configuration. Classification syntagms, for instance, realize a 'kind of' relation between participants by means of a composition in which the participants are symmetrically arranged on the picture space, are of equal size (even when in reality they are not), and have the same distance between them and the same horizontal and vertical orientation. This suggests that they all belong to the same category. In such syntagms, the relation between the participants is represented as a stable and quasipermanent relation, rather than in terms of an action or event.

Images can also realize interpersonal meaning through (1) size of frame, which can bring depicted elements closer to the viewer or keep them at a distance; (2) angles, which can confront viewers directly with depicted participants or represent the relation as more oblique, and which can place viewers either above or below depicted participants; and (3) through the gaze of depicted participants, which can address viewers directly and so realize a symbolic 'demand' (for sympathy, respect, sexual interest, etc, depending on the accompanying facial expressions and/or gestures) or address the viewer indirectly and so create a barrier between the represented world and the word of the viewer.

Textual meanings are visually realized by three aspects of composition: the placement of the elements of a composition in the visual space (top or bottom, left or right, center or margin); the relative salience of the elements; and the degree to which the elements are separated from each other by frame lines, empty space, or other visual devices. These aspects of visual structuring apply not only to the elements of pictures but also to the elements of layouts (e.g., headlines, pictures, blocks of text), so that analysis can reveal, for instance, the relative salience of text and image and the way they are compositionally related.

Kress and van Leeuwen's approach therefore allows an integrated analysis of the visual and linguistic aspects of written text. The analyst can ask, for instance, which participant is visually the Actor and which participant is linguistically, or discover that the image addresses the viewer directly, while the text does not.

O'Toole's theory of visual communication (1994) also takes its inspiration from the linguistics of Halliday and is in many ways complementary to Kress and van Leeuwen's approach. Like Kress and van Leeuwen, O'Toole takes Halliday's metafunctions as his point of departure and assigns specific visual systems to specific metafunctions. But unlike Kress and van Leeuwen, he also introduces rank, analyzing visual communication as building 'figures' from 'members,' 'episodes' from 'figures,' and 'pictures' from 'episodes' in the same way that language builds words from morphemes, groups from words, clauses from groups, and clause complexes from

clauses. Specific systems of visual grammar realize each of the three metafunctions at each of the four ranks. 'Representational' meanings, for instance, may be realized by 'actions and events' at the rank of picture, 'groups and subactions' at the rank of episode, individual 'characters' at the rank of figure, and 'parts of the body' at the rank of member. Perspective is one of the systems that realize what O'Toole calls 'modal' meanings at the level of picture, 'relative prominence' one of the systems that realize it at the rank of episode, 'gaze' one of the systems that realize it at the rank of figure, and so on.

The functional approach to the study of word and image has been applied in a number of fields and has also been extended to film (van Leeuwen, 1996; Iedema, 2001) and new media (Lemke, 2002; Kress, 2003). The journal *Visual Communication* regularly publishes papers by scholars working with this approach.

Ethnomethodology and Conversation Analysis

The relation between word and image (or, more broadly, the visual) has also been approached from the perspectives of ethnomethodology and conversation analysis. Charles Goodwin (e.g., 2001), Heath (e.g., 1986), and others have focused on the way professional discourses interpret images and other visual phenomena in quite specific ways that often differ markedly from commonsense interpretations. In the court proceedings following the police beating of Rodney King, for instance (Goodwin, 2001: 175–178), the crucial evidence was a videotape that actually showed police officers beating King. Yet the police officers were acquitted, at least in the first trial, because of the testimony of an expert witness who interpreted the video in terms of professional police codes for determining aggressive intent. Specific movements were interpreted as being at the start of an "aggression spectrum" (2001: 176):

> Witness: It is starting to be [aggressive]
> (pointing) This foot is laying flat
> (pointing) There's starting to be a bend
> (pointing) this leg
> (pointing) in his butt
> (pointing) the buttocks area has started to rise
> which would put us at the beginning of our spectrum again

Goodwin and others have also argued for the inclusion of the gaze and other visual signifiers (e.g., pointing) in conversation analysis transcripts, showing that without those signifiers it is often impossible to determine what drives the specific moves that conversation analysts are interested in (e.g., restarts, repairs). This can be of crucial importance in areas such as the study of medical interaction.

Typography

Even though typography is perhaps the most obvious visual aspect of written language, it has until recently been ignored by linguists. Crystal is an exception (1998: 7):

> The explication of printed language needs the expertise of both typographers and linguists, in order to provide a complete description of its forms and structures and a satisfactory explanation of its functions and affects.

New technologies such as the word processor have made typographic expression available to everyone, and as a result linguists also are becoming more aware of it (e.g., Graddol, 1996). Overall, however, they have not gone much beyond categories that are well established in the typographical literature, such as the difference between the classic serif and the modern sans serif and between text and display fonts, the former requiring, in the first place, legibility and clarity, the latter leaving more space for typographic expression (e.g., in relation to brand names, titles, logos, and so on). Walker's book on the subject (2001), in the series 'Language and social life,' describes many of the rules and prescriptions that govern everyday uses of typography, although not in a specifically linguistic framework. Van Leeuwen (2005) used the concepts of connotation and metaphor to discuss typographic meaning and in more recent work (in press) argued for the semiotization of the 'distinctive features' of typography, thus both adapting and extending Jakobson and Halle's 'distinctive feature theory' of phonology. He argues that the distinctive features of letter forms (e.g., weight, roundedness versus angularity, regularity versus irregularity) lend themselves more easily to metaphoric extension than whole letter forms. Roundedness, for instance, can, depending on the context, signify organic, natural, feminine, and so on. As a given font combines several distinctive features, several such metaphors may resonate in it.

Many contemporary typographers are interested in blurring the boundaries between images and letter forms by 'iconizing' either the letter forms themselves and/or the way they are arranged on lines and pages. In this way they regain a connection that had been lost in the development of the alphabet. Typography is also increasingly multimodal, using not only the elements of letter forms, bowls, stems, ascenders, descenders, serifs, and so on, but also color, texture, 3-dimensionality, and movement. Journals such as

Visible Language, *Information Design Journal*, and *Visual Communication* regularly publish in the area.

Conclusion

Linguists have only recently begun to pay attention to the many forms of visual expression and structuring in written texts. As the importance of visual communication grows in many areas, including, for instance, education, science, workplace literacy, and global communication, the study of word and image is likely to undergo rapid growth in the near future. As Kress has said (2003: 168), the major task facing us now:

> . . . is to imagine the characteristics of a theory which can account for the processes of making meaning in the environments of multimodal representation in multimediated communication . . . . Such a theory will represent a decisive move away from the assumptions of mainstream theories of the last century about meaning, language, and learning.

Word Classes/Parts of Speech: Overview

J Anward, Linköping University, Linköping, Sweden

© 2006 Elsevier Ltd. All rights reserved.

The word-class system of a language is a classification of the individual elements that make it up, viz., words, in terms of properties that determine their use in syntax and their contribution to meaning.

Such a classification was proposed for Classical Greek by Dionysius Thrax (2nd century B.C.), and it has remained the single most influential word-class system since then. Dionysius used clusters of morphological, syntactic, and semantic properties in his word-class definitions, which are rendered in condensed form below (Robins, 1990: 39). Note that, Dionysius often used the broader term 'part of speech,' roughly equivalent to recurring meaningful unit, instead of 'word.'

Noun: a part of speech inflected for case, signifying a concrete or abstract entity, with general or specific reference.

Verb: a part of speech without case inflection, but inflected for tense, person, and number, signifying an activity or process performed or undergone.
Participle: a part of speech sharing the features of the verb and the noun.
Article: a part of speech inflected for case, preposed or postposed to nouns.
Pronoun: a part of speech substitutable for a noun and marked for person.
Preposition: a part of speech placed before other words in composition and in syntax.
Adverb: a part of speech without inflection, in modification or in addition to a verb.
Conjunction: a part of speech binding together the discourse and filling gaps in its interpretation.

Apollonius Dyscolus (1st century A.D.) and Priscian (6th century A.D.) adapted Dionysius's classification to Latin. Latin has no articles, so 'article' was replaced by 'interjection' in order to keep the number of word classes constant. Moreover, Priscian changed the order of 'adverb' and 'preposition.' The latter change may seem insignificant, but interestingly, Priscian held that he listed the word classes in their natural order. And this claim actually makes some sense.

Dionysius's and Priscian's word-class systems are primarily based on a morphological classification of words. Nouns (and articles and pronouns) are inflected for case but not for tense. Verbs are inflected for tense but not for case. Participles are inflected for both case and tense, and all other words are uninflected.

This morphological classification is then combined with a syntactic classification. All word classes except noun, verb, and participle, which are used as heads of subjects and predicates, are characterized as to syntactic function. Articles modify nouns, and pronouns substitute for nouns. Adverbs modify verbs. Prepositions modify both nouns and verbs. Interjections do not combine with other words, and conjunctions join all kinds of words.

Finally, nouns and verbs are characterized as to meaning, in terms of the Aristotelian categories of substance and quality (nouns) and activity and passivity (verbs). More contemporary notions corresponding to these categories would be entity (for substance), property (for quality), and event (for activity and passivity). Priscian's system is summarized in Table 1.

As we can see now, Priscian's list is built on two ordering principles: nonmodifiers (heads, in modern terminology) before modifiers before other functions; and nouns before verbs before 'both,' i.e., words with both nominal and verbal inflection or words that can modify both nouns and verbs. The ordering of nouns before verbs is motivated by their semantic characterizations. Nouns, which denote the semantically and ontologically primary category of substance, 'must' come before verbs, which denote the semantically and ontologically secondary categories of activity and passivity. Presumably, the syntactic functions of noun and verb as subject and predicate, respectively, follow from these semantic characterizations.

In the following, a possible modernization of the classical word-class system will be sketched, taking advantage of a mixed tradition of studies from the last hundred years (Jespersen, 1924; Brøndal, 1948; Lyons, 1968; Hopper and Thompson, 1984; Schachter, 1985; Croft, 1990; Hengeveld, 1992; Stassen, 1997; Anward, 2000).

We gain in generalizability if we substitute a contrast between nominal morphology, i.e., inflection for definiteness, number, gender, case, and/or possessor agreement, and verbal morphology, i.e., inflection for finiteness, tense, mood, aspect, subject agreement, and/or object agreement, for the simple contrast between case and tense. And we now know that there are languages without nominal morphology and languages without verbal morphology. Yoruba has neither nominal nor verbal morphology, and Kobon has only verbal morphology, for example (Anward, 2000). There may also be considerable overlap between nominal and verbal morphology. Possessor agreement is often identical to either subject agreement or object agreement (Allen, 1964; Seiler, 1983). There are also languages in which there is identity between nominal inflection and either finiteness inflection or subject agreement. Nama is a case in point.

Table 1 Priscian's world class system

	Morphological criteria	*Syntactic functions*	*Semantic categories*
noun	[+case; −tense],		substance and quality:
verb	[−case; +tense],		activity and passivity:
participle	[+case; +tense]:		
article	[+case; −tense]:	noun modifier	
pronoun	[+case; −tense]:	noun substitute	
adverb	[−case; −tense]:	verb modifier	
preposition	[−case; −tense]:	noun and verb modifier	
interjection	[−case; −tense]:	independent	
conjunction	[−case; −tense]:	'joiner'	

Sometimes such overlaps seem to suggest a fundamental similarity of nouns and verbs. For example, in Eskimo languages, ergative case and genitive case are largely identical. Since possessor agreement and absolutive agreement are identical as well, and core arguments of both nouns and verbs precede their heads, this has often been interpreted as indicative of a neutralization of the noun–verb distinction in Eskimo languages (Johns, 1992, but cf. Woodbury, 1985).

When it comes to syntactic functions, the simplest contemporary theories hold that phrases and clauses are built in the same general way, consisting of a head, which is constructed with arguments (subject, objects, complements) and modifiers. In *I was born one morning when the sun didn't shine*, for example, *was* is the head, which is constructed with two arguments, *I* (subject) and *born* (subject complement), and one modifier, *one morning when the sun didn't shine*. Furthermore, phrases and clauses can be conjoined with units of the same type.

Syntactic functions that figure in word-class definitions are typically just those: predicate (head of a clause), argument, and (argument or predicate) modifier, in addition to the traditional functions of independent and 'joiner.'

Contemporary theories that recognize subject, object, and/or complement as distinct functions obviously need a broader set of defining syntactic functions.

Finally, a reasonable list of semantic categories would be situation, entity, event, quantity, property, relation, place, and time.

Table 2 would then show the defining clusters of properties for each word class.

In Classical Greek and Latin, adjectives, such as *original*, quantifiers, such as *many*, and numerals, such as *one*, all look very much like nouns from a morphological point of view and were thus not differentiated from them by Dionysius and Priscian. It was only when the classical definitions were applied to modern Western European languages, in which the morphological differences between nouns and the other word classes are greater, that adjectives, quantifiers, numerals, and demonstratives were recognized as separate classes.

However, words are not limited to just one cluster. Consider *morning*, for example, which can be used not only as predicate modifier, time, as in *I was born one morning*, but also as argument, entity, as in *morning has broken*, and as argument modifier, time, as in *in the early morning rain*. A word has rather a characteristic distribution over the full range of clusters.

A consequence of this is that every cluster in the table need not be associated with its own word class in a language. In particular, all of the modifier classes (adjective, numeral, quantifier, adverb, preposition, and subjunction) are cross-linguistically optional. Instead, nouns, verbs, and/or other modifier classes can be extended to the various modifier functions. Verbs, or a particular class of verbs, can be used as argument modifiers and/or predicate modifiers. An example of this is stative verbs in Ainu (Shibatani, 1990: 19, 80):

Table 2 A modernized world class system

Word class	*Syntactic function*	*Semantic category*	*Type of morphology (if any)*
nouns & pronouns	argument	entity	nominal
verbs	predicate	event	verbal
numerals & quantifiers	argument modifier	quantity	nominal
adjectives	argument modifier	property	nominal
adverbs	predicate modifier	quantity/ property	none
adpositions, subjunctions	modifier	relation/ place/ time	none
interjections	independent	situation	none
conjunctions	joiner	relation	none

(1a) ku-pirka
1SG-good
'I am good'

(1b) pirka menoko
good woman
'pretty woman'

(1c) pirka inu
good listen
'listen well'

Nouns, or a subclass of nouns, may have a similarly wide distribution, as in the classical languages.

A language may also lack a distinct class of adverbs, using adjectives as predicate modifiers. Swedish is an example of this:

(2a) tåget var långsamt
the.NEUT-*train was slow*-NEUT
'the train was slow'

(2b) de åt långsamt
they ate slow-NEUT
'they ate slowly'

While 'interjection' seems to be a universal part of speech, it is a matter of considerable controversy whether all languages have a noun–verb distinction. In some languages, such as the Wakashan languages Nootka and Nitinat (Nootka) (Swadesh, 1939; Whorf, 1945) and the neighboring Salish languages (Kuipers, 1968; Kinkade, 1983; Jelinek and Demers,

Table 3 Distribution over syntactic functions. An example

argument	*sin*	*sins*	*sinner*	*sinners*				
predicate	*sin*	*sins*			*sinned*			
argument modifier						*sinning*	*sinful*	
predicate modifier						*sinning*		*sinfully*

1994), all content words (as opposed to invariable particles) are said to be basically verbal, or predicative, in nature but also to allow an argument use, in which they are interpreted essentially as headless relatives. In other languages, such as Eskimo languages (Hammerich, 1951; Johns, 1992), all content words are held to be basically nominal, with agentive nouns as the closest equivalent to verbs. In yet other languages, such as various Austronesian languages (Himmelmann, 1991; Broschart, 1997), it is not even clear which function, predicate or argument, is basic. Indeed, Gil (1994) has argued that in such languages, all words are basically interjections, which can be extended to all other functions.

Moreover, a language need not use all syntactic functions. A language may lack predicate modifiers, using sequences of clauses to express roughly the same notions. Yoruba is one such language (Lord, 1993). A language may also lack argument modifiers, using predicate modifiers to express what would be expressed by argument modification in other languages. Hixkaryana and other Carib languages are examples of languages that approximate this type (Derbyshire, 1979).

In polysynthetic languages, syntactic functions may, optionally or obligatorily, be realized word internally, through compounding, incorporation, and/or inflection. In particular, argument function may be restricted to pronominal inflection, with independent nouns being used as appositions (Jelinek, 1984), and predicate and argument modification may be essentially word-formation processes. Whorf (1945), Sasse (1988), Hengeveld (1992), and others have proposed that there are languages that lack arguments altogether and express everything through a series of predicates. However, proposed examples of such languages, in Wakashan and Iroquoian languages, do not really seem to fit the type (Jacobsen, 1979; Mithun, 2000).

An interesting problem arises when word classes are defined by a range of clusters of morphological, syntactic, and semantic properties: how to treat words that are similar in form and meaning. Consider, for example, the words *sin, sins, sinner, sinners, sinned, sinning, sinful, sinfully.* Part of their distributions over syntactic functions is shown in Table 3.

What is not always made clear in descriptions of word-class systems is whether we are seeing here one word, the noun *sin*, and its distribution over a range of clusters, or several words, the nouns *sin* and *sinner*, the verb *sin*, the adjective *sinful*, and the adverb *sinfully*, and their respective distributions. If the latter position is adopted, it is typically linked to a distinction between inflection (which does not change word class) and derivation (which may). There is no easy solution to this problem, but it is of utmost importance to keep it in mind when dealing with word-class systems.

Word Formation

L Bauer, Victoria University of Wellington, Wellington, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

The term 'word formation' is ambiguous in modern linguistics. In one usage of the term, it is equivalent to 'morphology' and refers to matters such as affixation and reduplication as used in the creation of word forms.

In the more widely accepted sense of the term, word formation refers to the creation of new lexemes in a given language. Thus it specifically excludes inflectional morphology, such as that which makes *manages* and *managed* from the base *manage*. At the same time, it may include things that are only marginally considered to be morphology, or that may be excluded from morphology. For example, there is some dispute (at least implicitly) in the literature as to how far blending is a matter of morphology, but blending to create new lexemes such as *stagflation* or *chunnel* is part of word formation. Similarly, alphabet-based formations such as abbreviations (*etc*. from *et caetera*), initialisms (*SIA* pronounced as a series of letters from *Singapore International Airlines*), and acronyms (*IJAL* pronounced /aɪdʒæl/ from *International Journal of American Linguistics*) are not usually considered to be morphological, but they are part of word formation. Similarly, the creation of rhyme-based forms like *teeny-weeny* or ablaut-based forms like *tittle-tattle* are clearly part of word formation in English, but less clearly part of morphology. Other types that may be relevant are diminutives and hypocoristics in languages that use them very productively. Less clearly relevant are English forms like *unbe-bloody-lievable* and *poet shmoet*, which are not necessarily controlled by all English speakers, and which, as yet, do not appear to create generally recognized neologisms. It has even been argued that compounding, which is generally accepted as word formation, is part of syntax rather than part of morphology.

There are, however, some ways of forming new dictionary items that are not included as word formation. Specifically, these are semantic modifications such as widening and narrowing and figurative extensions of meaning for already existing forms.

Word Formation

L Bauer, Victoria University of Wellington, Wellington, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

The term 'word formation' is ambiguous in modern linguistics. In one usage of the term, it is equivalent to 'morphology' and refers to matters such as affixation and reduplication as used in the creation of word forms.

In the more widely accepted sense of the term, word formation refers to the creation of new lexemes in a given language. Thus it specifically excludes inflectional morphology, such as that which makes *manages* and *managed* from the base *manage*. At the same time, it may include things that are only marginally considered to be morphology, or that may be excluded from morphology. For example, there is some dispute (at least implicitly) in the literature as to how far blending is a matter of morphology, but blending to create new lexemes such as *stagflation* or *chunnel* is part of word formation. Similarly, alphabet-based formations such as abbreviations (*etc.* from *et caetera*), initialisms (*SIA* pronounced as a series of letters from *Singapore International Airlines*), and acronyms (*IJAL* pronounced /aɪdʒæl/ from *International Journal of American Linguistics*) are not usually considered to be morphological, but they are part of word formation. Similarly, the creation of rhyme-based forms like *teeny-weeny* or ablaut-based forms like *tittle-tattle* are clearly part of word formation in English, but less clearly part of morphology. Other types that may be relevant are diminutives and hypocoristics in languages that use them very productively. Less clearly relevant are English forms like *unbe-bloody-lievable* and *poet shmoet*, which are not necessarily controlled by all English speakers, and which, as yet, do not appear to create generally recognized neologisms. It has even been argued that compounding, which is generally accepted as word formation, is part of syntax rather than part of morphology.

There are, however, some ways of forming new dictionary items that are not included as word formation. Specifically, these are semantic modifications such as widening and narrowing and figurative extensions of meaning for already existing forms.

Word Grammar

R Hudson, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Overview

'Word grammar' (**WG**) is the name of a theory of grammar in which words play a specially central role as the main unit of syntax; for example, the syntactic structure of (1) recognizes just four units, one per word, and phrases play no explicit part in the grammar:

(1) Small children often cry.

This rejection of phrase structure was the main distinctive feature of WG at the time when it received its name (Hudson, 1984), but the focus of the theory has broadened since then to include the outlines of a general theory of conceptual knowledge, with language as a particular subcase. The psychological assumptions are, by and large, conservative and uncontentious, but the linguistic theory that results is rather different from most mainstream theories and belongs firmly in the recent tradition of 'cognitive linguistics' (e.g., Barlow and Kemmer, 2000). This article will present some of the psychological assumptions (in the sections 'Inheritance Networks' and 'How to use a Network'), but will mostly be concerned with their consequences for the theory of language structure.

As far as language is concerned, the leading idea is (2):

(2) Language is a network.

This was already explicit from the early days (Hudson, 1984: 1) but its implications are much clearer now. 'Inheritance Networks' will spell out the nature of this network in more detail, and will highlight the importance of is-a relations (as in 'John is-a linguist' or 'BUT is-a conjunction') and its related logic, default inheritance. This logic is more fully developed in WG than in any other theory of language structure (Hudson, 2003b); for example, it is default inheritance that explains the difference:

- between regular and irregular morphology
- between basic and special word order
- between a morpheme's basic shape and its allomorphs
- between sense and referent
- between types and tokens.

In fact, it is tempting to conclude that default inheritance is responsible for all the complexity (and flexibility) in language. However, it is important also to

Overview

'Word grammar' (**WG**) is the name of a theory of grammar in which words play a specially central role as the main unit of syntax; for example, the syntactic structure of (1) recognizes just four units, one per word, and phrases play no explicit part in the grammar:

(1) Small children often cry.

This rejection of phrase structure was the main distinctive feature of WG at the time when it received its name (Hudson, 1984), but the focus of the theory has broadened since then to include the outlines of a general theory of conceptual knowledge, with language as a particular subcase. The psychological assumptions are, by and large, conservative and uncontentious, but the linguistic theory that results is rather different from most mainstream theories and belongs firmly in the recent tradition of 'cognitive linguistics' (e.g., Barlow and Kemmer, 2000). This article will present some of the psychological assumptions (in the sections 'Inheritance Networks' and 'How to use a Network'), but will mostly be concerned with their consequences for the theory of language structure.

As far as language is concerned, the leading idea is (2):

(2) Language is a network.

This was already explicit from the early days (Hudson, 1984: 1) but its implications are much clearer now. 'Inheritance Networks' will spell out the nature of this network in more detail, and will highlight the importance of is-a relations (as in 'John is-a linguist' or 'BUT is-a conjunction') and its related logic, default inheritance. This logic is more fully developed in WG than in any other theory of language structure (Hudson, 2003b); for example, it is default inheritance that explains the difference:

- between regular and irregular morphology
- between basic and special word order
- between a morpheme's basic shape and its allomorphs
- between sense and referent
- between types and tokens.

In fact, it is tempting to conclude that default inheritance is responsible for all the complexity (and flexibility) in language. However, it is important also to

recognize the important role played by another very general principle of processing, variable binding, which will be explained in 'How to Use a Network.' Both default inheritance and variable binding are heavily dependent on spreading activation.

Language structure, as such, is completely declarative – as indeed it has to be if it is a network. It is like a map, which may be used as a guide for action but which is not, in itself, either an active machine or even a set of instructions for actions. Language is simply a (very large) collection of nodes and their (even larger) set of interconnecting links. However, the network is highly structured through a rich classification of the nodes and links, so (unlike distributed connectionist networks) this theory is easy to compare with more conventional theories based on rules and lexical items. For example, entities in language are of a small number of basic types that define the traditional levels of language – semantics, syntax, morphology, and phonology. This structure will be outlined in 'Levels of Language.' Similarly, links fall into a fairly traditional range of categories that are specialized for particular places in the total network – e.g., for linking a word to a meaning, an affix to a stem, or one word to another. However, although the categories used for classifying links are mostly quite traditional, WG is the only formal theory of language (or knowledge) that allows links to be freely classified in just the same way as entities.

If language is a network as described here, and if this network is a subnetwork of general knowledge, then language cannot be modular in the very strong sense of this word (Fodor, 1983). Neither language, nor any of its parts (e.g., syntax), is informationally encapsulated so that elements inside it cannot communicate directly with elements outside it. On the contrary, it is quite typical for elements of language to be closely related to nonlinguistic categories such as speaker types and situations – e.g., people only use *cookie* if they are American and *gee-gee* when speaking to children. However, networks do allow more limited kinds of modularity, including subnetworks whose elements have relatively dense internal links and relatively sparse external ones.

The network theory also favors explanations of language structure in functional rather than genetic terms. If language has the same formal properties as the rest of knowledge, its formal properties need no special explanation, genetic or otherwise. Moreover, even the substantive properties – the particular categories and relations – are rather easy to learn by induction from experience (Tomasello, 2000), so the contents of the network can be explained by a theory of learning and we can conclude that language is not an 'instinct' (Pinker, 1994).

Inheritance Networks

If language is a network, then a major research question is how it fits into a general typology of networks: what kind of network is it? This question can be approached either quantitatively or qualitatively. Graph theory takes a quantitative approach by applying various kinds of mathematical measure to a network. For example, what is the average topological distance – i.e., the average number of links in the shortest path – between nodes? Many complex human networks, such as society and the internet, turn out to have quite small distance averages, so they are called small worlds (Barabási, 2003); research so far indicates that the same may be true of language (Ferrer i Canchol and Solé, 2001; Motter *et al.*, 2002). Another quantitative question is whether the number of links per node has a normal distribution (like that of people's heights) or whether it follows a power law, with a small number of extremely richly connected nodes and a long tail of nodes with very few connections. The second kind of network, called scale-free, also turns out to be common among complex human networks; and once again language too seems to have this property (Ferrer i Canchol and Solé, 2001).

Linguistics, unlike graph theory, is concerned with the qualitative characteristics of the language network. WG is not the only linguistic theory that has concerned itself with the question. The whole of synchronic linguistics in the 20th century was an attempt to flesh out Saussure's idea that "language is a system of interdependent terms in which the value of each term results solely from the simultaneous presence of the others" (Saussure, 1959: 114 – in short, a network of terms. However, given the enormous size of a language, it is easy to lose sight of the total network in order to focus on some small area such as phonology or syntax, so most theories say very little about the overall structure of the network of relations. Indeed, this methodological preference has turned into the factual claim that language really is modular (Fodor, 1983), with distinct submodules that have quite different organizing principles – "a modularization of the grammar reminiscent of the modularity of the mind" (Smith, 1999: 68). The first fully articulated theory to stand back and consider the total network of language was stratification grammar (Lamb, 1966) and its more recent manifestation called neurocognitive linguistics (Lamb, 1998). Lamb's ideas played a major part in the development of WG (in spite of the negative comment in Hudson, 1990: 15, but WG's claims about the language network are different from Lamb's.

According to WG, language, like the rest of conceptual knowledge, is an inheritance network. What this means is that:

- the classification relation is-a has a special status, because it allows generalizations by default inheritance (discussed more fully below).
- every node is part of at least one inheritance hierarchy united by is-a; for instance: TAKE is-a Verb is-a Word. In other words, all nodes are classified.
- every link is also part of at least one inheritance hierarchy, such as Object is-a Complement is-a Dependent. Thus, classification applies not only to nodes but also to links.

Because of its privileged status, the is-a relation has a special notation: a small triangle whose base is next to the super-category. Figure 1 shows an elementary WG diagram for the examples just given.

Choosing to model language as a network is not simply a choice of notation. As we shall see in 'How to Use a Network,' it has important implications for understanding how we use language, but it also affects the purely linguistic analysis of the language system. The main effect is that categories have to be justified carefully because of the following general principle:

(3) Every category is defined, and distinguished from other categories, solely by its links to other categories.

The first consequence of this principle is that strictly speaking, the labels that we give to nodes and links carry no information at all, so a network would still carry exactly the same information even if we removed all labels (Lamb, 1998: 59). Universal categories identified only by their name fit very badly into WG theory. Another consequence is that labels should not be used, as in most other theories, to show class membership. For example, if something is a noun, this fact should be shown by an is-a link to Noun, rather than by labeling it 'noun.' Labels should not be used in order to smuggle classificatory information into the network.

Nodes are simply nodes – points where links meet. The function of a node, in fact, is merely to show a correlation between two or more links. In this sense, then, a node defines some 'property'; for example, an Object link from TAKE represents the property of taking an object. Each link can in fact be seen as defining a property for mathematical sense: a relation that takes an argument and yields a unique value for it (compare the mathematical function +2 which gives a unique value for any number to which it is applied). As in mathematics, the value varies with the argument; for example, the value of the object function varies from verb to verb and from token to token, so at the level where generalizations are made about objects of all verbs, the value must be a variable. In WG notation, variables are shown either as a simple dot or (perhaps more helpfully) as a question-mark: '?'. Clearly (3) requires that this labeling convention must duplicate some kind of relation difference, but it is not yet clear what this difference is. Variables will play an important role in the WG theory of processing outlined in 'How to Use a Network.'

Figure 2 shows a simple network including the dependencies and word types distinguished in Figure 1. It shows that a word's complement is normally impossible: its quantity ('#') is 0. This general ban on complements explains why, unlike adjuncts, they are selected by specific lexical items, which can override the general ban as explained in the next paragraph; for example, TAKE has an obligatory object (whose quantity is 1). Figure 2 also shows that objects are nouns, so this property also applies by inheritance to the object of TAKE.

As explained earlier, the main characteristic of inheritance networks is the possibility of generalization by default inheritance. This seems to be the basic logic

Figure 1 Inheritance hierarchies for nodes and links.

Figure 2 A network for TAKE and its object.

Figure 3 Default inheritance.

of everyday reasoning, in which we generalize from the typical case in order to guess information that we cannot observe. For example, if we recognize something as a cat we assume it has four legs, like the typical cat; in other words, this cat inherits (in our minds) the properties of the typical cat by default, in the absence of information to the contrary. However, if we already know that it has only three legs this information overrides the default so we can continued to classify it as a cat in spite of the exceptional leg number. The same logic applies to linguistic reasoning:

- by default, a dependent is optional,
- but if a dependent is (more specifically) a complement, it is impossible,
- but if a complement is (more specifically) the object of TAKE, it is obligatory.

In each case, a fact located lower in the inheritance hierarchy of entities or relations takes priority over one located above it. The logic is presented more formally in Figure 3, where the double-headed arrow means an arrow going in either direction and the crossed lines mean that the link concerned is not already present.

Default inheritance is controversial among logicians because it is nonmonotonic, meaning that it allows us to draw conclusions which later turn out to be false. It is also controversial in computational linguistics because the system spends a great deal of time checking for possible overriders. However, a network model reduces both objections to triviality because the search space for competitors is very small.

Levels of Language

We turn now to the specifics of language structure. WG distinguishes the traditional levels of language through its classification of entities and relations rather than by trying to divide all the data of linguistics into discrete components, which has the advantage of avoiding boundary disputes. The relevant node types are as follows:

- words of all degrees of generality from word tokens (e.g., *tokens* in this sentence) through lexemes (e.g., TOKEN) to inflectional categories (Plural) and word classes (Noun) and even the category Word itself,
- forms of all sizes from morphemes (e.g., {s}) to word forms (e.g., {tokens}), and of all degrees of generality from tokens to form classes (e.g., Suffix),
- sound segments of all sizes and generalities,
- letters and other units of written language,
- any kind of entity or relation may act as the meaning (see 'Semantics and Sociolinguistics' section) of a word.

Figure 4 The architecture of language.

Various kinds of sets of these entities are also needed; for example, word strings are used in coordination (see 'Syntax' section).

As for relations, they fall into a range of types that include the following, all of which are relevant to language; the terms in brackets are specific subcases of the more general relation which heads the paragraph:

- Meaning (or referent) links a word to its meaning.
- Realization (base or fully inflected form) links a word to its component morphemes, or larger form, and also links a form to its phonological structure. (Written structures may realize forms directly or indirectly through phonology.) Realization may even be considered the converse of Meaning, in which case it is also found between words and their meanings.
- Co-occurrent (dependent, next, etc.) links a word to words that co-occur with it. It also handles the combinational patterns of co-occurring morphemes, sounds, and letters, and indeed may be found in semantics (e.g., as semantic roles such as Actor).
- Part (part 1, last part, etc.) links a larger form to the smaller forms within it, and is also found in many other areas of knowledge. Part may also include Member, which relates a set to its parts.

The overall architecture of language is summarised in Figure 4. One of the noteworthy features of this diagram is the absence of a separate lexicon. In WG,

Figure 5 Derivational and inflectional morphology.

Figure 6 Morphosyntactic relations between words and variants.

as in other cognitive theories (Langacker, 2000), the difference between lexical and more general facts is merely a matter of degree; for example, the valency facts about TAKE are shown in the same network as those for more general categories such as Verb and Word (Figure 2).

Morphology

The only level of language in Figure 4 that needs justification is morphology, the level whose units are forms, which are distinguished in notation by the use of the traditional morpheme boundary markers, {. . .}. For example, the form {dog} is distinguished from the word DOG as well as from the phonological structure /dog/. Forms are morphomic (Aronoff, 1994), so:

- unlike words they have no meaning or syntactic categorization
- and unlike phonological units they have no pronunciation – indeed, they correspond just as easily to written structures.

The relation between a form and its corresponding word is Realization, not Part, i.e., abstractness, not size. The size relation applies to different forms, so we find complex forms that contain smaller ones; e.g., {dogs} contains {dog} and {s}, and {farmers} contains {farmer}, which in turn contains {farm} and {er}.

The WG treatment of morphology rests on the familiar distinction between two kinds of word: lexemes (e.g., DOG) and inflections (e.g., Plural). Thanks to default inheritance, unmarked inflections can be treated simply as the default, so DOG is by default singular in contrast with its plural, DOG:-plural. Only the marked form needs any mention in morphology. This distinction between lexemes and inflections allows a distinction between two kinds of Realization relation: Base and Fully inflected form (abbreviated to 'fif'). A word's base is determined by its lexeme and its fif by its inflection. By default the base and fif are the same, but marked inflections distinguish them in some way. This is the province of inflectional morphology, while derivational morphology deals with the relations between the bases of different lexemes, e.g., between those of FARM and FARMER. The difference between derivational and inflectional morphology is shown schematically in Figure 5.

Although derivational and inflectional morphology are very different at the level of words, at the level of form they offer the same range of possible morphological differences. These differences are each defined by a morphological function called a variant, so for example, the plural form is the s-variant of the base and the agent noun is the er-variant of the source base. This treatment of morphological structure is an important (and controversial) part of WG theory because it establishes a clear separation between morphological structure and its syntactic and semantic correlates. The morphosyntactic realization relations of inflectional and derivational morphology map lexemes and inflections onto variants, while the morphophonological relations map variants onto morphological and (eventually) phonological structures. The morphosyntactic mapping is shown in Figure 6, in which the variants have replaced the unlabeled relations of Figure 5.

One of the immediate benefits of this separation of morphosyntax from morphophonology lies in the treatment of syncretism, cases where the same morphological pattern realizes more than one word type. To take an obvious example, the s-variant pattern is used not only for plural nouns (e.g., {dogs}), but also for present tense singular verbs (e.g., {eats}). More

interestingly, the passive and past participles of English verbs are always the same however irregular the verb may be. This can be explained by saying that both inflections use the same variant of the base, the en-variant (Hudson, 1990: 90).

Variants are the bridge from words to morphological structure. In simple cases, the variant of a form consists of a copy of that form combined with an affix ({farm} + {er} or {farmer} + {s}). These patterns are handled in terms of parts, with Part1 and Part2 occurring in that order. This kind of pattern is illustrated in Figure 7 for the er-variant, of which the relation between {farm} and {farmer} is an example.

Exceptions are easily accommodated thanks to default inheritance, as shown in Figure 8. This illustrates two degrees of irregularity: suppletion ({person}, {people}), where the entire base is replaced, and vowel-change ({goose}, {geese}), where only the vowel is changed. Of course, morphology can be a great deal more complicated than the examples discussed here, but WG has already been shown to be able to accommodate various kinds of complexity such as multiple affixation and cliticization (Camdzic and Hudson, 2002; Creider and Hudson, 1999; Hudson, 2001).

Syntax

The most distinctive characteristic of syntax in WG is the rejection of phrase structure in favor of dependency structure, which follows from the network assumption (2). The question is not whether to show dependencies between words, but how. Phrase structure identifies dependencies indirectly via part relations to phrases, whereas dependency analysis recognizes them directly. Consider this very simple example:

(4) Gas smells.

Linguistics would generally accept the traditional view that *gas* is related to *smells* in a way that explains, for example, the {s} on {smells}. The question is how to include such word–word relations in a syntactic structure. Phrase structure recognizes a number of phrase nodes, including (at least) an NP node, some kind of clause or sentence node, and (probably) a VP node. The relation between *smells* and *gas* is merely implied by phrase structure (such as the rather conservative one in Figure 9) but is explicit in a dependency structure.

The dependency analysis fits well in a general network-based theory of language, where all relations are shown explicitly. In contrast, standard phrase structure is incompatible with network theory because word–word relations are merely implicit. Indeed, it is not at all obvious that a phrase really is more than the sum of its parts, so the basis for WG syntax is not only that a phrase really is more than the sum of its parts, so the basis for WG syntax is not only that word–word dependencies must be part of the network because they are psychologically real, but also that phrases should be excluded from the network because they are psychologically real, but also that phrases should be excluded from the network because they are not real. A good analogy outside language is social structure. Interpersonal relations are certainly real, but groups such as families and communities are much more nebulous and hard to define; for example, where are the boundaries of 'my family' and – even worse – 'my community'? At best, the case for such groups needs to be made,

Figure 7 Variation by affixation.

Figure 8 Suppletion and vowel change.

and similarly for phrases in syntax; but all the standard arguments for phrases simply ignore the possibility of using word–word dependencies instead. However, even if phrases really are indispensable, this will merely show that phrases are needed in addition to dependencies, as in some proposed mixed theories (Hudson, 1976). Meanwhile, the WG answer is that every generalization that can be stated in terms of phrases can be stated at least as well in terms of dependencies between single words (Hudson, 1990: 104).

Suppose that linguistic knowledge is a network. It then follows that sentence structure is also a network with the same flexibilty as other networks For example, there is nothing in the network idea to prevent one word from depending on more than one other word; and in fact all the familiar evidence for structures such as raising and extraction shows that this possibility is reality. The structure in Figure 10 illustrates the kind of richness that is possible in a quite ordinary sentence:

(5) What do you think we should wait for?

Of course, there are limits to possible dependency structures and, as in any other theory of syntax, our aim is to find and explain them. For example, the dependencies in Figure 10 follow a very general principle:

(6) The dependencies in a sentence must include a tangle-free substructure, i.e., one in which the implied phrases do not overlap.

Figure 9 Phrase structure or dependency structure?

This is the substructure shown above the words. In contrast, sentence (7) is impossible because its dependencies do not include a tangle-free substructure.

(7) *I complicated like sentences.

The structure for (7) is shown in Figure 11, which is ruled out by (6). It is easy to imagine functional explanations for the restriction in (6); for example, it helps the hearer to identify word–word relations, and speaking is easier if one phrase is finished before the next one is started.

As mentioned earlier, the syntax of coordination is handled in terms of word strings, which are mere unstructured strings of words, like the strings that are possible as object of SAY:

(8) He said, "One, two, three, testing, testing."

A coordination is itself a word string consisting of two or more smaller strings (conjuncts) linked by a conjunction. However, the ordinary rules of syntax also apply to these strings, subject only to one extra constraint:

(9) Any dependency between a word inside one of the conjuncts and a word outside the entire coordination must also apply to one word inside each of the other conjuncts.

In other words, conjunction-reduction must apply across the board. Word strings are indicated in the notation by brackets, as illustrated in Figure 12. It is important to notice how this example shows that word strings are not phrases: for example, *London on Tuesday* is not a phrase in terms of any phrase-structure analysis.

Syntax is the level of language at which WG has been applied most intensively, so further details are easily available in the literature (Hudson, 1984, 1990, 1998, 1999, 2003a, 2003c).

Semantics and Sociolinguistics

The similarities between semantics and sociolinguistics are at least as striking as their differences. Semantics handles (at least) referential meaning, such as the

Figure 10 A syntactic structure.

Figure 11 An ungrammatical structure.

Figure 12 Coordination of non-phrases.

difference between apples and pears or between singular and plural, while sociolinguistics deals (at least) with the social meaning of words such as *hello* and *ain't*. However, as the terms imply, in both cases we are concerned with a kind of meaning, information about the world that follows from the choice of words. In both cases, this information can be inferred by anyone who is aware of the correlation between the word and the thought; for example, between the word *apple* and the concept Apple, and between *hello* and Meeting. In terms of spreading activation (which I discuss more fully in the next section), the word activates the thought, and both participants know that the same is true for both of them. In short, by using words "we can shape events in each other's brains with exquisite precision" (Pinker, 1994: 15). This is equally true of referential or social information. Moreover, there is a great deal of overlap between the two kinds of meaning; for example, the difference in (10) and (11) between polite and blunt imperatives could be classifed in either way:

(10) Do come in!

(11) Come in!

WG distinguishes the two kinds of meaning in terms of relations. Referential meaning is a property of the referent (the person or thing being referred to), whereas social meaning generally belongs to the speaker or the addressee (or both). In both cases, the particular individual is classified in terms of some general category: the sense for the referent, and some general social category for the speaker and addressee. We can illustrate both kinds of meaning in the name MOMMY, which refers to the mother of a child who is either speaking or being addressed, as in:

(12) Mommy will be back soon.

The advantages of a network analysis are especially obvious in a case like this where linguistic categories are related to non-linguistic ones. The WG analysis is shown in Figure 13, which treats Mother as a relation between two variables.

Figure 13 Referential and social meaning of MOMMY.

Figure 14 Classification by variable binding.

As might be expected in a highly lexicalized theory, WG has been applied quite extensively to problems of lexical semantics (Hudson and Holmes, 2000, Hudson, 2005), but one of the great advantages of dependency analysis in syntax is the relatively simple relation between syntactic dependencies and semantic relations. The published WG literature includes serious proposals for the semantic structure of plurals and quantifiers (Hudson, 1990: 139–146), past tenses and imperatives (Hudson, 1990: 222–223), and the semantic phrasing of arguments (Hudson, 1990: 146–151). However it has to be admitted that all these proposals need to be fleshed out.

Social meaning also benefits greatly from the network approach. In this case, one of the strengths of the approach is that it allows links to have different strengths; these are an essential ingredient of the model for spreading activation and are highly relevant to the quantitative work that has been so successful in recent sociolinguistics (Hudson, 1996: Chap. 7, 1997).

How to Use a Network

One of the attractions of a network model of language is the bridge that it offers between theoretical linguistics and psychology, where models of long-term memory are standardly framed in terms of networks (Reisberg, 1997: Chap. 7). Our knowledge of language, according to network models, is an example of long-term memory, but recent theories of working memory suggest that this too can be modeled in the long-term network: "Working memory is closely linked to LTM, and its contents consist primarily of currently activated LTM representations" (Miyake and Shah, 1999: 450). If these theories are right, then linguistic processing depends crucially on activity in the language network.

Figure 15 Enrichment by default inheritance.

WG now includes the basis for a theory of how processing works. It assumes, as already explained, that all long-term memory for language is held in a declarative network, but it also assumes that the links and nodes of the network have levels of activity that can be represented as numbers. This activity spreads in a completely mechanical way from active nodes to their neighbors, and the aim of processing is to allow nodes to compete for selection as the target meaning (in understanding) or as the target pronunciation (in planning). This far the model is similar to many others (e.g., Levelt *et al.*, 1999), but there are two crucial differences:

- The WG processor can create new nodes and links, which is not generally allowed in other theories of processing. A new node is created for each new token of experience, and for each property inherited by default inheritance (see Figure 3).
- WG processing is oriented toward the processor's current goals and interests, defined by highly active nodes and links; for example, a hearer's goal of finding meanings is reflected in the high activation of the Referent relation, and the hearer's interpretations are heavily biased by the general-knowledge nodes that are currently active.

The processor uses a small number of very general processes:

- Node and link creation, as described above, which creates new variable nodes (by default inheritance) and new constant nodes (for tokens).
- Variable binding, in which any highly active variable node is bound to the most active node that has the same super-category. This is how the processor assures the best fit between the token and the stored knowledge (Hudson, 1990: 46–52).
- Default inheritance, which again is controlled by activity so that it only applies to highly active variable nodes. This restriction prevents pointless inheritance that leads nowhere.

In principle this theory applies equally to productive and receptive processing, but for simplicity we can consider just one direction, reception (i.e., understanding). Suppose we hear the sounds [pat], and we have the form {pat} in our vocabulary. Hearing the sounds activates their respective nodes, which in turn activates the form {pat}, which contains all of them (in the right order). However, that activation does not itself tell us that we have just heard {pat}; to reach this conclusion we must first create a node for the unidentified form, which we can call {form-X}, together with an is-a link to the general category Form and a variable node '?' for its super-category. The latter node is highly active (thanks to both newness and the links to the active sounds [pat]), so variable binding automatically binds '?' to the most active node which is-a Form, namely {pat}. The effect of variable binding can be seen in Figure 14.

Once {form-X} is classified as an example of {pat}, it can be enriched by inheriting the latter's realization relations to words such as the name PAT and the verb PAT; this change is shown in Figure 15.

Activation then spreads blindly along these inherited realization relations to the word nodes, where it may meet activation flowing from nodes that are already active, such as the one for a person called Pat. Any highly active variable nodes will in turn inherit from their super-category, e.g., the name PAT, and so on until the word's referent is found, the processor loses interest, and activation dwindles.

This theory of processing is currently (2004) being modeled computationally in a program called WGNet++. Information about this and other developments in WG can be found at the WG site.

Word Order and Linearization

A Siewierska

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 9, pp. 4993–4999, © 1994, Elsevier Ltd.

Word order and linearization are major areas of linguistic inquiry within all linguistic traditions: descriptive, theoretical, and typological. This article concentrates on the typological perspective centering on the notion of 'basic order.' It begins with a consideration of the notion of basic order, then proceeds to review the distribution of word order patterns on a cross-linguistic basis, and next presents a brief account of the host of interrelated factors deemed to underlie the recurring linearizations. The article closes with a specification of the major problems posed for theory specific accounts of universal word order phenomena.

The Notion of Basic Order

In the wake of Greenberg's (1963) seminal investigation, the order of major clausal constituents has been characterized in terms of the relative positioning of the subject (S), object (O), and verb (V), giving rise to a typological classification of languages into SVO, SOV, VSO, OVS, VOS, and OSV. Since most, if not all, languages exhibit some variation in the ordering of major clausal constituents, the characterization of a language with respect to the above six-way typology is achieved in relation to the meta-theoretical concept of basic order. Within the context of typological studies the term basic order, at the sentence level, is typically identified with the order that occurs in stylistically neutral, independent, indicative clauses with full noun phrase (NP) participants, where the subject is definite, agentive, and human, the object is a definite semantic patient, and the verb represents an action, not a state or an event. It is important to note that for reasons to be specified presently, the basic order, defined as above, may, but need not, correspond to the statistically dominant word order in a language. The identification of the basic order of a language has a limited heuristic value in that it does not correlate with a unified set of word order properties on a cross-linguistic basis. Nonetheless, enough significant sub-regularities of order have been observed to follow from the basic order to warrant taking the Greenbergian typology as a point of departure for further examinations of universal word order phenomena (*see* **Greenberg, Joseph H. (1915–2001)**).

In view of the above-mentioned requirements imposed on the constituents of clauses in terms of which the basic order is defined, the determination of the basic order of a language is not always a straightforward matter. For instance, in some ergative languages it is not always clear which constituent of a transitive clause should be considered as subject and which as object, owing to the conflicting results obtained from the typical subject identifying criteria. Another problem arises in connection with the necessary presence of two full NP participants. There are languages in which such transitive clauses are nonexistent (e.g., Puget Salish) or uncommon (e.g., Apalaí, Gunwinggu, Yatzachi, Zapotec) since the subject and/or object must or tends to be expressed solely by pronomial affixes on the verb or by clitics elsewhere in the clause. Two or more word order patterns may be in competition for basicness as in languages such as Guugu–Yimidhirr, Sahaptin, or Samoan, which exhibit considerable word order variation at the sentence level. This variation is conditioned by the distribution of given and new information or the relative newsworthiness of the informational content of the constituents of the utterance. Furthermore, some languages display different word order preferences dependent on text types. Russian is a case in point, as it is seen to favor SVO order in the formal written language but SOV in the colloquial spoken language.

The above problems notwithstanding, unique decisions as to the nature of the basic order can be made for the vast majority of language.

Distribution of Basic Orders of Major Clausal Constituents

The relative frequency of occurrence of the six basic orders has been established and confirmed by several independent investigations. Table 1 lists the percentage of languages exhibiting each of the six basic orders in the language samples of Greenberg (1963), Ruhlen (1975), Mallinson and Blake (1981), Hawkins (1983), and Tomlin (1986).

As suggested by the figures in Table 1, in terms of frequency of occurrence, the six basic orders fall into two subgroups: subject-before-object languages and object-before-subject ones. The former are widely attested, while the latter did not feature in Greenberg's original sample at all, and subsequently have been found to occur in less than 5% of the world's languages. Of the subject-before-object languages SOV and SVO by far outnumber the VSO ones, and among the three linearization patterns in which the object precedes the subject, OSV is the rarest.

Sampling Techniques

The language frequencies reflected in the data in Table 1,with the exception of Tomlin's (1986) figures, are based on random language samples. Consequently, though the above figures provide a good indication of the frequencies of the six basic orders among the world's languages, the cross-linguistic preferences and to a lesser extent dispreferences that they define cannot be automatically assumed to be due to inherently linguistic factors underlying the nature of human language, as opposed to nonlinguistic forces such as

Table 1 Frequency of six basic orders in the world's languages

	SOV	*SVO*	*VSO*	*VOS*	*OVS*	*OSV*
Greenberg (142)	45.0	36.6	18.3	—	—	—
Ruhlen (427)	51.5	35.6	10.5	2.1	—	0.2
M & B (100)[a]	41.0	35.0	9.0	2.0	1.0	1.0
Hawkins (336)	51.8	32.4	13.3	2.3	—	—
Tomlin (402)	44.8	41.8	9.2	3.0	1.2	—

[a]In Mallinson and Blake's sample 11 languages are not classified in terms of this typology. Therefore the percentages in this row do not add up to 100.

genetic affiliation, areal distribution, typological structure, and cultural identification. Particularly in need of investigation is the impact of nonlinguistic influences on the frequency of basic orders displaying relatively similar levels of occurrence such as SOV versus SVO or the three object-before-subject orders. For example, it is generally claimed that there is no linguistic preference for SOV as compared to SVO order, since the slightly higher frequency of SOV languages is not statistically significant. Yet several linguists have pointed out that in Tomlin's (1986) language sample, which is the most representative of the language samples cited in Table 1, 40% of the SVO languages are Niger–Congo. Therefore, had it not been for various historical factors which led to the expansion of the Niger–Congo language family, the frequency of SVO would have been markedly lower, and by the same token the linguistic preference for SOV languages much clearer. Historical factors may also be responsible for the relatively high frequency of occurrence of VSO as compared to the object-before-subject languages, since the majority of VSO languages belong to the Austronesian language family.

In order to minimize the genetic, areal, and cultural biases inherent in random sampling, new sampling methodologies are being applied involving stratified language samples as discussed by Perkins (1989). The proposed language samples, such as those developed by Rijkhoff *et al.* (1993), seek to select a proportional number of maximally differentiated languages, both areally and genetically, the latter criterion being sensitive not only to variation across language families, but also to variation within individual phyla. These more representative language samples will provide a better understanding of the interplay between linguistic and nonlinguistic determinants of order and thus contribute substantially to a fuller appreciation of the universal and particular features of human language.

Typological Markedness

Since around 95% of the world's languages display basic orders in which the subject precedes the object, such ordering is seen to be typologically unmarked, while the converse object-before-subject order is labeled as marked. The source of the difference in markedness of the two word-order patterns is a topic of continuing debate. The dominant view associates the different markedness values with differences in ease of processing, and the adoption of the respective linearizations with the instantiation of an addressee-oriented principle of communication in the case of subject-before-object languages as opposed to a speaker-oriented communicative strategy in the case of object-before-subject ones.

The basic properties of subjects and objects in the two groups of languages are by and large the same: subjects tend to be human, semantically agentive, and moreover topical and therefore they typically convey given information, whereas objects are generally inanimate, semantically nonagentive, frequently focal and thus informationally new. Psycholinguistic research summarized in Bock (1982) suggests that the processing of easily accessible language data, where high accessibility correlates with the above-mentioned features of subjects, involves an 'automatic' processing mode and contrasts with the 'controlled' processing of less accessible language material. It is therefore argued that the presentation of easily accessible language data before less accessible information, as is the case in subject-before-object orders, facilitates syntactic processing since it frees both the speaker's and the addressee's processing resources for the controlled processing of the less accessible material. Moreover, the automatically processed data provides the basic frame or perspective for the interpretation of the utterance; hence the processing task of the addressee is made easier if this perspective is presented first. Conversely, presenting new or more newsworthy and thereby less accessible information first, as in object-before-subject orders, is seen to impede the addressee's cognitive processing, in view of the fact that the relevance of the material delivered earlier in the utterance does not become apparent until the whole utterance is complete.

The communicative strategy adopted by the dominant subject-before-object languages is viewed as addressee-oriented because the speaker, having some new or news-worthy information to deliver, places the addressee's need for clarity and distinctiveness above his own need to divulge the message. In object-before-subject languages, on the other hand, the addressee's need of a prior perspective for the interpretation of the utterance is sacrificed to the immediate interests of the speaker, and hence the speaker-oriented view of such word-order patterns. The addressee versus speaker orientation underlying the markedness value of subject-before-object as compared to object-before-subject ordering is currently regarded as a major source of typological markedness in general. It is argued that though human language is geared to serve both speakers and listeners, it is intrinsically more difficult for the listener to decode the message than for the speaker to encode it, since the speaker has knowledge of what is going to be said, but the listener does not. Consequently, an optimal communicative system should be biased toward the addressee rather than the speaker. Though requiring further verification, the fact that the source of the markedness contrast between subject-before-object as

compared to object-before-subject languages may follow from a more general principle of markedness must be regarded as a significant finding of typological research.

The Natural Serialization Principle

Greenberg's (1963) six-way division of languages into SOV, SVO, VSO, OVS, VOS, and OSV has been supplemented by a two-way typology of VO and OV languages originating in the dependency tradition and the work of the nineteenth-century German typologists. This two-way typology is based on the division of constituents into head/modifier pairs such as: verb/object, verb/adverbial, auxiliary/main verb, noun/adjective, noun/relative clause, noun/genitive, noun/determiner, adposition/noun phrase, adjective/adverbial (where the first member of the pair is the head and the second the modifier).

The basic insight of the VO/OV typology is expressed by Vennemann's (1972) natural serialization principle (NSP) and its analogs, which stipulate that languages show a preference for serializing constituents in terms of either the head > modifier schema (VO, centrifugal) or, modifier > head pattern (OV, centripetal). Languages exhibiting linearization patterns in complete conformity with the NSP are termed 'consistent.' Consistency, however, is currently viewed not as a norm, but as an ideal which languages approximate to various degrees. Thus, for example, given that the subject qualifies as a modifier of the verb, all SVO languages are by definition inconsistent. And of the languages in Greenberg's Appendix II, 95 (67 percent) are inconsistent in terms of just five head/modifier pairs, i.e., verb/object, verb/subject, adposition/noun, noun/adjective, and noun/genitive. Of these 95 languages, 57 are inconsistent with respect to 1 of the 5 head/modifier pairs, and 38 with respect to 2. Both the number of inconsistent languages and the degree of inconsistency increase once other head/modifier pairs are considered.

In view of the fact that the vast majority, if not all, languages exhibit a measure of inconsistency the word order predictions incorporated in the NSP have been refined by supplementary principles which seek to specify among the inconsistent orderings the regularities that do obtain.

Supplementing the NSP

A number of subregularities of order of a high level of generality have been captured by Hawkins (1983) in the principle of cross-category harmony (PCCH). The PCCH states that languages display a preference to generalize the order obtaining in one head/dependent category to that of other categories. Departures from this preference in one head/dependent category are in turn likely to induce comparable departures in other head/dependent pairs. Thus, for example, Hawkins notes that the continuum in verb position, verb-initial, verb-medial, verb-final, is reflected in the position of the noun in relation to its modifiers. This is shown by the fact that VSO languages are more consistently noun-initial than SVO languages, in which the preposing of the subject in relation to the verb is often mirrored by the preposing of the adjective and/or genitive and/or determiner before the noun. Moreover, nonrigidly verb-final SOV languages (SOV languages which allow for the placing of some modifiers to the right of the verb) tend to have some nominal modifiers following the noun, while rigidly verb-final SOV languages generally serialize all their modifiers prenominally.

Recurrent patterns have also been found to underlie the inconsistent placement of modifiers relative to the noun, negative elements relative to the verb or verb stem, and the location of conjunctions and subordinators. Of particular interest is the cross-linguistic distribution of noun/modifier pairs. Hawkins (1983: 75, 86), using a typological division of languages based on the presence of prepositions (prepositional languages) vs. postpositions (postpositional languages) – which he takes to be superior to the two-way verb-based typology – considers the statistical frequency of the ordering of noun/modifier pairs and in particular the patterns of preposing a modifier before the noun in prepositional languages, and of postposing a modifier after the noun in postpositional languages. He observes that in the case of prepositional languages, the first to be preposed are the demonstrative or numeral; then both; next comes the adjective; followed by the genitive; and finally the relative clause. This is captured in the prepositional noun modifier hierarchy (PrNMH) (1):

(1) $\text{Prep} \supset ((\text{NDem} \vee \text{NNum} \supset \text{NA}) \;\&\; (\text{NA} \supset \text{NG}) \;\&\; (\text{NG} \supset \text{NRel}))$

The postposing of modifiers in postpositional languages begins with the adjective; then comes the relative clause; then the demonstrative or numeral; and finally the genitive. The order of modifier postposing is represented in the postpositional noun modifier hierarchy (PONMH) (2):

(2) $\text{Post} \supset ((\text{AN} \vee \text{RelN} \supset \text{DemN} \;\&\; \text{NumN}) \;\&\; (\text{DemN} \vee \text{NumN} \supset (\text{GN}))$

The principle underlying the two-noun modifier hierarchies is the preference for placing 'lighter' constituents to the left of 'heavier' ones (see Sect. 4.3). Given the progressive increase in length and complexity and thereby heaviness from the demonstrative to

the relative clause, the PrNMH is fully consistent with the light > heavy principle, the PoNMH only partially so, namely in that relative clauses tend to be postposed earlier than demonstrative or numerals. Significantly the predictions captured in the two-noun modifier hierarchies are corroborated by the actual quantities of languages displaying the stipulated co-occurrences. Thus, for example, there are more prepositional languages in Hawkin's sample in which a numeral is placed before the noun (44), than those with a prenominal demonstrative (38) or genitive (19), and there is only one language with a preposed relative clause.

Ordering Relations Among Modifiers

The NSP stipulates a preference for serializing modifiers either to the right or to the left of the head, but it says nothing about the relative ordering of modifiers among each other. The most general principle pertaining to the sequencing of modifiers (as compared to the ordering of modifier pairs) takes the form of a constraint against discontinuous constituents which ensures that a modifier will be separated from its head only by other modifiers of the same head. The most notable departures from this norm leading to discontinuities within noun phrases and adjectival phrases are to be found among the languages of the Australian continent, and also in several European languages such as Russian, Polish, or Latin. More widespread are instances of discontinuity involving relative clause and PP extraposition, subject-raising, and parenthetical placement, all of which require special pragmatic motivation. The ordering characteristics of modifiers among each other have been captured in the form of several related principles, the most important of which are discussed briefly below.

Iconicity

Any facet of structure – thus also any word order pattern – which corresponds to the order of things in the real world and which reflects generally accepted perceptions of dominance and salience and/or established semantic dependencies may be viewed as iconic (Haiman, 1985). One of the manifestations of iconicity (*see* **Iconicity**), thus broadly conceived, is subject and/or object selection, and linearization in line with what is known as the personal hierarchy (3):

(3) 1 person > 2person > 3person human > higher animals > other organisms > inorganic matter > abstracts

The personal hierarchy reflects the unqualified interest of humans in the ego, their conversational partners, and other humans over and above nonhuman entities or abstract situations and events. It predicts a preference for clauses with human or animate subjects such as *People are dying of starvation* rather than inanimate or abstract ones such as *Starvation is killing people* which is consistently adhered to on a cross-linguistic basis. Apart from the effect that the personal hierarchy exerts on linearization via subject and also object selection, its influence is often observed in the linear arrangement of clitics and bound pronouns, and in the order of conjuncts. In the latter case, however, it may interact with considerations of social status, relative authority, and politeness as evinced by the formal *you and me* as compared to the colloquial *me and you*. Essentially iconic is also the strong correlation between subjecthood and agentivity mentioned in Sect. 2.2, which is seen to reflect a preference for presenting events and situations in line with the actual development of things in the real world. Our perception of natural progression in the case of an action event is from the agent to the patient and for an act of giving from giver to receiver. The choice of agent for subject over that of patient or recipient is thus consistent with both the perceived directionality of events and the dictates of the personal hierarchy.

Under the broad view of iconicity may be subsumed virtually all of the other principles of order that have been proposed to date including the ones to be mentioned in the following sections. More commonly, however, by iconic ordering is meant ordering in line with actual temporal succession. The effect of temporal ordering is discernible particularly in the placement of adverbials and conjuncts. For example, in Mandarin a projected destination is positioned preverbally, a destination already reached postverbally. In English source tends to be placed before destination or goal as in *on the road from Amsterdam to Rotterdam* rather than *on the road to Rotterdam from Amsterdam*. As for conjuncts, in numerous languages, conjuncts generally serialize in ordered sequences such as: first, second … last; beginning, middle, end; anterior, posterior; or a, b, … z, etc., as reflected in expressions like: *in and out*; *there and back*, or *at sixes and sevens*.

Semantic Bonding

The claim inherent in the principle of semantic bonding is that the tighter the semantic link between a modifier and the head, the closer the modifier is likely to be located to the head. The influence of this principle may be observed in the sequencing of the verbal arguments and adjuncts, the ordering of different types of adjectives and adverbials and also in the placement of bound morphemes relative to the stem.

As regards the verbal arguments, the direct object and verb are seen to form a more cohesive semantic and syntactic whole than the subject and verb. This fact in turn is taken to underlie the cross-linguistic infrequency of basic VSO as compared to SOV and SVO orders and the extreme rarity of OSV vis-à-vis the slightly less rare OVS and VOS. To the tight semantic bond between the object and verb is also attributed the tendency to place indirect objects and verbal adjuncts either to the left or the right of the verb–object sequence. This tendency is especially strong in SVO languages in which SVXO orders are found only in heavily restricted sets of circumstances. SOV languages are more permissive in this respect; there are some SOXV languages, and the ones which display SXOV basic order may have SOXV as an option. Nonetheless, the preservation of the integrity of the verb and object combination may be assumed to provide the motivation for the relatively frequent SOVX ordering.

Differences in semantic bonding have also been observed between the verb and its adjuncts. For example, adjuncts designating instruments, speed, or manner specify additional properties of the situation or event denoted by the predicate and its arguments and thus may be viewed as entering into a close semantic relation with the nucleus of the predication. A looser semantic bond exists between the nucleus predication and adjuncts of location, time, or frequency since they do not affect the nature of the designated situation or event, but merely define its spatial or temporal location. Even more loosely related to the predication are epistemic, evaluative, and evidential adjuncts which reflect the speaker's evaluation of or attitude towards the content of the predication while not actually contributing to the semantic content of the predication itself. And the most distinctly linked to the predicate nucleus are illocutionary adjuncts which modify the force of the basic illocution of the utterance. Though the order of verbal adjuncts even more so than that of the arguments is subject to the effect of pragmatic factors, a preference has been discerned for linearizations reflecting the just-noted degrees of semantic bonding. For instance, in the English clause *Honestly, you certainly performed brilliantly yesterday* the illocutionary adverb *honestly* precedes the subjective epistemic adverb *certainly*, and the manner adverbial *brilliantly* is placed closer to the predicate than the temporal adverbial *yesterday*. The semantic modifications introduced by adjuncts can also be expressed morphologically by bound forms, the ordering of which relative to the stem tends to reflect the same semantic scope relations as in the case of adjuncts. For example, the preferred order of application of 'aspect,' 'tense' and 'modality' markers relative to the stem of the verb is either verb–ATM or MTA–verb.

Turning to the modifiers of the noun, the adjective and noun form a semantic whole, while the numeral adds only cardinality, and the demonstrative designates proximity and/or identifiability. In keeping with the principle of semantic bonding, the preferred order of prenominal modifiers is ADJNUMDEM–N and the most frequent order of postnominal ones is N–ADJNUMDEM (Hawkins, 1983: 119–20).

Length and Complexity

The length and complexity of an element is seen to covary inversely with the ease with which its referent can be identified. Identifiability in turn correlates closely with frequency of occurrence and high topicality. Since easily accessible and topical information tends to be placed prior to less accessible material (see Sect. 2.2), by the same token shorter and less complex constituents tend to precede longer and more complex ones.

There is compelling cross-linguistic evidence for the preference to place informationally and structurally light constituents before heavy ones. The following are just a few cases in point:

- the tendency for clitics to occur in second position in the utterance, known as Wackernagel's Law;
- the earlier placement of pronomial as compared to nominal subjects or objects in languages such as Bimoba, Cairene Arabic, German, Grebo, Ila, Karen, Twi, and Uzbek;
- the preference for final placement of sentential NPs observed in, for example, Blackfoot, Tuscarora, Kinyarwanda, Malagasy, Sherpa, Persian, Latin, and English;
- the phenomena of heavy NP shift as in *Fred sent to his client several brochures with all the accommodation details* and extraposition from NP as in *I met a man last night who reminded me of you*;
- the prehead vs. posthead placement of shorter as compared to longer forms of a modifier as is the case with: relative clauses in, for example, Finnish, German, and Tagalog; inflectional and prepositional genitives in several Germanic languages (e.g., *the boy's uncle* vs. *the uncle of my next-door neighbor*); and simple as opposed to complement-taking adjectives in English (e.g., *a proud man* vs. *a man proud of his son*.

Word-order Variation

The significance attributed to the concept of basic order follows from the assumption that the basic

location of functional categories will be maintained unless there are reasons to do otherwise. These reasons may involve pragmatic high-lighting, the varying identifiability or salience of the constituents of the clause, or language-specific considerations such as those following from the verb-second constraint in some of the Germanic languages. Variations in order resulting from the above, typically involve major clausal constituents rather than the elements of noun, adjective, or adpositional phrases, which on the whole display rather stable word-order characteristics.

The number and type of permissible word-order permutations at the sentence level differs from language to language. All languages appear to allow for the initial placement of at least some temporal and spatial adverbials and for the fronting of emphatic and contrastive constituents. Also common are variations in order resulting from the placement of heavy material to the right, mentioned earlier. Interestingly enough, variations in order induced by this tendency even occur in object-before-subject languages which on the whole exhibit word order preferences counter to those displayed by subject-before-object languages.

The potential variations in the positioning of the verb, its arguments, and adjuncts are not predictable from the basic order that a language displays. Linguists have, however, noted a close relationship between a language's basic syntactic order and its positional strategies for the topic and the focal part of the comment; the subject position is the most common location of the topic, and the object position the characteristic location of items in focus. Therefore certain predictions can be made in regard to the most likely placement of constituents bearing particular pragmatic functions, though not concerning the extent to which such placement is actually utilized or the range of constituents that it typically affects. For example, both English and Polish are typically classified as SVO languages, and as one would expect, in both languages the initial position is viewed as the favored location of the topic. Yet in English the placement of nonsubject topics in initial position (particularly of verbal arguments and instruments and benefactives) is highly constrained; OSV and XSV orders as in *Max I like* or *In Kuwait he was born* are unquestionably marked. Whereas in Polish the initial placement of topical objects or adjuncts occurs regularly and is conditioned by the same factors as those affecting the initialization of subjects. Needless to say, Polish sanctions much greater variation in order than English does; in fact in Polish virtually any sequence of the verb and its arguments and adjuncts is possible.

Accounting for Word Order in Grammatical Theory

The typological classification of languages in terms of the basic location of the subject, object and verb, and the preference for modifier/head or head/modifier ordering offers only a restricted amount of information about the word-order patterns to be found in any given language. Nevertheless, it constitutes a good point of departure for theory-specific accounts of linearization. However, since most languages are not consistent in the NSP sense of the term and moreover allow for some variations on the basic order, the formulation of linearization rules capable of capturing the full range of word-order patterns encountered in languages has so far met with comparatively little success. Most grammatical frameworks, for instance, government and binding, lexical functional grammar (*see* **Lexical Functional Grammar**), generalized phrase structure grammar, categorial grammar (*see* **Categorial Grammars: Deductive Approaches**), word grammar (*see* **Word Grammar**), and relational grammar seek to provide an account only of a limited subset of word-order facts, typically those which the theories in question define as syntactic as opposed to pragmatic. And even within such reduced domains they have encountered problems, arising in the main from the failure to include an appropriately wide range of information in the specification of rules of order. For instance, the constituency-based rules of order proposed in the context of lexical functional gammar, do not allow for the inclusion of functional information, nor information pertaining to semantic roles or semantic features such as animacy or definiteness. Since the order of objects in ditransitive clauses and often also the sequencing of clitics is in many languages affected by the above factors, no adequate account of the relevant ordering can be given within the proposed system of rules. To give another example, the linear precedence rules of generalized phrase structure grammar do not make reference to the internal composition of phrases. Therefore the possibility of PP > NP order with heavy NPs in English cannot be accounted for, nor the postnominal location of adjectives taking PP complements.

The complex array of factors that affect word order cross-linguistically and the interrelationships among these factors suggest that the word-order patterns occurring in languages are best viewed not in terms of dichotomous grammaticality judgments, but in terms of a series of choices defining a preferential ranking among the set of word-order possibilities available in a given language. This needs to be captured in any word-order rules that aspire to provide

a comprehensive statement of order. Currently, ways of doing this are being elaborated, which assign a relative weighting to each of the possible orderings and specify how conflicting tendencies defining mutually exclusive linearizations are likely to be resolved within individual languages and across languages. This line of research represents the first serious attempt to integrate syntactic, semantic, and pragmatic aspects of order within specific models of grammar and therefore, in view of the far from satisfactory treatment of word order in modern grammatical theory, undoubtedly, is a step in the right direction.

What are the processes that the brain engages in when making the journey from a visual input of intersecting lines and curves to making contact with meaning? This question has stimulated considerable research since the days of Cattell (1886), generating findings that inform not only psycholinguistics but also domains as diverse as computational modeling (Plaut *et al.*, 1996; Coltheart *et al.*, 2001), automatic and attentional processes (Neely, 1977), pattern recognition (Selfridge and Neisser, 1960), and the neural substrates of language processing (Petersen *et al.*, 1988). Research at the word level is particularly tractable and revealing as words are well-defined units that can be analyzed and processed at various levels (i.e., spelling, sound, grammar, meaning; Balota, 1994).

How Is Word Recognition Studied?

There are many procedures that researchers have developed to study the processes involved in word recognition. For example, in perceptual identification, words are visually degraded by masking or brief presentations, and subjects are asked to identify them, with identification accuracy being the dependent measure. In eye-tracking studies, subjects' eye movements (e.g., fixation, location, and duration) are tracked as they read text. In semantic categorization tasks, subjects are asked to classify words (e.g., is *dog* an animal?), with response latency and accuracy being the dependent measures. In neuroimaging studies, inferences about the processes involved in word recognition are made from on-line measures of the time course and location of neural activity via event-related potentials, positron emission tomography, or functional magnetic resonance imaging. Researchers also study individuals with isolated disruptions in reading (specific subclasses of dyslexia) to better understand normal reading.

Although each of these approaches has benefits, there are also some costs (see Balota *et al.*, 2004). Hence researchers continue to rely most heavily on two relatively simple tasks (lexical decision and naming) to study isolated word recognition. In speeded lexical decision, subjects are presented with either a real word or a nonword (e.g., *flirp*), and they are required to make the word/nonword discrimination

a comprehensive statement of order. Currently, ways of doing this are being elaborated, which assign a relative weighting to each of the possible orderings and specify how conflicting tendencies defining mutually exclusive linearizations are likely to be resolved within individual languages and across languages. What are the processes that the brain engages in when making the journey from a visual input of intersecting lines and curves to making contact with meaning? This question has stimulated considerable research since the days of Cattell (1886), generating findings that inform not only psycholinguistics but also domains as diverse as computational modeling (Plaut *et al.*, 1996; Coltheart *et al.*, 2001), automatic and attentional processes (Neely, 1977), pattern recognition (Selfridge and Neisser, 1960), and the neural substrates of language processing (Petersen *et al.*, 1988). Research at the word level is particularly tractable and revealing as words are well-defined units that can be analyzed and processed at various levels (i.e., spelling, sound, grammar, meaning; Balota, 1994).

How Is Word Recognition Studied?

There are many procedures that researchers have developed to study the processes involved in word recognition. For example, in perceptual identification, words are visually degraded by masking or brief presentations, and subjects are asked to identify them, with identification accuracy being the dependent measure. In eye-tracking studies, subjects' eye movements (e.g., fixation, location, and duration) are tracked as they read text. In semantic categorization tasks, subjects are asked to classify words (e.g., is *dog* an animal?), with response latency and accuracy being the dependent measures. In neuroimaging studies, inferences about the processes involved in word recognition are made from on-line measures of the time course and location of neural activity via event-related potentials, positron emission tomography, or functional magnetic resonance imaging. Researchers also study individuals with isolated disruptions in reading (specific subclasses of dyslexia) to better understand normal reading.

Although each of these approaches has benefits, there are also some costs (see Balota *et al.*, 2004). Hence researchers continue to rely most heavily on two relatively simple tasks (lexical decision and naming) to study isolated word recognition. In speeded lexical decision, subjects are presented with either a real word or a nonword (e.g., *flirp*), and they are required to make the word/nonword discrimination

as quickly and as accurately as possible. In speeded naming, words (and occasionally nonwords) are visually presented to subjects and their task is to pronounce the words aloud as quickly and accurately as they can. For both tasks, researchers are primarily interested in how quickly people name words or make lexical decisions across different experimental conditions, with the assumption that naming and lexical decision latencies reflect processes involved in accessing lexical representations (Seidenberg, 1990).

Clearly, no single task or method can fully capture the dynamics of lexical processing. A word recognition task measures both lexical processes and operations specific to that task. For example, the lexical decision task is sensitive to discrimination processes that are independent of lexical identification (Balota and Chumbley, 1984). Similarly, naming latencies are heavily influenced by a word's initial sound (Kawamoto and Kello, 1999). Consequently, there is a growing consensus that reading processes are best understood by considering converging evidence across multiple experimental paradigms (Jacobs *et al.*, 1998).

Models of Word Recognition

Many models have been proposed to explain how word recognition takes place (see Jacobs and Grainger, 1994 for a review). One of the earliest models proposed was the logogen model (Morton, 1970), which posits a word detector (logogen) for every word in the reader's lexicon. Each logogen possesses some resting level of activation, and when a word is presented, the logogen for that word accumulates evidence until some threshold is reached. At this juncture, word recognition takes place.

Using the logogen framework as a foundation, McClelland and Rumelhart (1981) developed a very influential computational model of letter and word recognition. The interactive activation model (IAM) contains three processing levels (visual, letter, word), with respective units within each level represented by a node (**Figure 1**). A visual input first stimulates feature-level nodes, which send activation to letter-level nodes, and on to word-level nodes (which correspond to logogens). Over time, each node reflects the activation spreading across the units, and one can test the effect of a variable by inspecting the value of a node after a given amount of time has passed. The IAM accounts for many findings in the literature. For example, the finding that people recognize frequently encountered words (*world*) more rapidly than rarely encountered ones (*glitch*), the word frequency effect, is reflected by the fact that high-frequency word nodes have lower recognition thresholds than low-frequency ones, and so require less evidence to be recognized.

One important aspect of the IAM is its parallel and cascadic nature. In particular, during word recognition, a word is not simply recognized independently of other words stored in the lexicon. Rather, many words receive activation, and the model eventually settles into the appropriate representation across time, via a set of facilitatory and inhibitory pathways. One finding that is consistent with the activation of multiple words en route to recognition is the orthographic neighborhood effect. An orthographic neighbor is a word that can be produced by another word by simply changing a single letter (see Coltheart *et al.*, 1977). So, for example, *can* has the neighbors *cap*, *cat*, *pan*, *con*, *man*, among many others. The orthographic neighborhood effect refers to the finding that words with many orthographic neighbors produce faster response latencies than words with few orthographic neighbors, with this effect being larger for low-frequency words. Hence, multiple lexical units appear to be activated when a single word is presented. Of course, one might have expected just the opposite pattern, because of inhibition of competitors, a prediction from the original IAM. Although more recent embellishments of components of the interactive activation model can accommodate orthographic neighborhood effects (see Grainger and Jacobs, 1996), this is an important area that is still being actively researched (see Andrews, 1997 for a review).

While the IAM describes how lexical access may occur, it does not consider how we read or pronounce words. The dual-route model of pronunciation

Figure 1 McClelland and Rumelhart's (1981) interactive activation model of word recognition. Copyright (1981) by the American Psychological Association. Reproduced with permission.

(Coltheart *et al.*, 2001) argues that at least two routes mediate spelling and sound (Figure 2).

The lexical route is very similar to the IAM, and simply maps the word's spelling onto its lexical representation to retrieve its pronunciation. In contrast, the sublexical route assembles the word's pronunciation using English spelling-to-sound rules (Venezky, 1970). For example, if a single-syllable word ends in 'e' then the preceding vowel is long, as in *save*. In principle, we need two routes because readers can pronounce irregular words such as *have* (which violate spelling-to-sound rules and hence cannot be correctly generated by them) and nonwords such as *flirp* (which have no lexical representation).

The dual-route model is supported by two other major pieces of evidence. First, although regular words are, on average, pronounced faster than frequency-matched irregular words (Baron and Strawson, 1976), this regularity effect is much larger for low-frequency words than for high-frequency words (Seidenberg *et al.*, 1984) (Figure 3). According to the dual-route model, high-frequency words (regular or irregular) can be pronounced quickly via the lexical route, before the sublexical route assembles a conflicting pronunciation. For low-frequency words, the lexical route is slower, and hence more susceptible to sublexical processes. In this situation, the two routes generate mismatching pronunciations for irregular words (e.g., for *pint*, the lexical route would generate the correct pronunciation, while the sublexical route would generate a pronunciation that rhymes with *hint*), and this conflict takes time to resolve. Early studies of acquired dyslexia also revealed a striking dissociation between the two routes. Individuals with phonological dyslexia (Patterson, 1982) can pronounce real words (that have lexical representations) but perform poorly for nonwords, suggesting a breakdown in the sublexical route. In contrast, individuals with surface dyslexia (Shallice and Warrington, 1980) tend to regularize irregular words (e.g., pronounce *broad* so that it rhymes with *road*), suggesting a breakdown in the lexical route.

Figure 2 Dual route model of pronunciation.

One or Two Routes? An Ongoing Controversy

An influential alternative to the dual-route model is Seidenberg and McClelland's (1989) connectionist model of naming and word recognition (see Plaut *et al.*, 1996 for an updated version). The model (Figure 4) contains an orthographic layer, which codes the spelling of the stimulus input, and a phonological layer, which represents the pronunciation of the stimulus output.

The network 'learns' to read (i.e., associate a word's spelling with its pronunciation) through repeated exposures to spelling–pronunciation pairs

Figure 3 Experimental results from the Seidenberg, Waters, Barnes, and Tanenhaus (1984: Experiment 3) study. Copyright (1989) by the American Psychological Association. Reproduced with permission.

Figure 4 Seidenberg and McClelland's (1989) triangle connectionist framework for lexical processing. Copyright (1997) by Psychology Press Ltd.

(based on their frequency in English), via a feedback procedure (called back propagation). When the output of the model is incorrect, the weights of the connections are gradually changed to more closely approximate the correct response. Importantly, the model can pronounce novel nonwords and simulate critical empirical findings like the frequency by regularity interaction, without explicit spelling-to-sound rules. Plaut *et al*. have thus argued that a single mechanism is sufficient for naming regular, exception, and novel items. Importantly, this model has distributed (rather than localist) word representations. There is no one-to-one mapping between words and nodes; instead, a single word is represented by multiple nodes.

While the connectionist model is not immune to criticisms (see Coltheart *et al*., 1993; Forster, 1994), it challenges the dual-route framework and provides a cogent alternative to it. Furthermore, the debate between one and two routes has ramifications beyond psycholinguistics. It also recapitulates the controversy between classical and connectionist models: is cognition supported by symbolic manipulation (dual route) or connectionist networks (single route)? In this instance, the contrasting models of reading function as paradigm cases for cognitive science (Perfetti, 1999).

Although considerable progress has been made in developing computational models of word recognition, these models have primarily focused on single-syllable word processing, in large part because large databases for multisyllabic words were not available. However, a web-based database of over 40 000 multisyllabic, polymorphemic words has recently been developed, containing both behavioral measures and a powerful search engine. Hopefully, this will help guide future work and extend these models into larger word units.

Context Effects on Word Recognition

Of course, words are most often not presented in isolation, but occur in the context of other words. Researchers have studied context effects in word recognition via both single-word context and studies that have manipulated sentence contexts. With respect to single-word contexts, there have been many studies of a phenomenon referred to as the semantic priming effect (see Neely, 1991 for a review). In this situation a prime is presented before a target word and one manipulates the relationship between the prime and the target (e.g., *doctor-nurse* vs. *carpet-nurse*). The intriguing finding here is that response latencies to the second word are faster when it follows a related prime than when it follows an unrelated prime, even though no overt response is required of the prime stimulus.

There appear to be least two important mechanisms that underlie priming effects (Neely, 1977). One is relatively slow and involves subjects attending to the relation between the prime and the target. For example, when presented with *doctor*, they may generate words that might follow and when one of the generated words is presented (e.g., *nurse*), they are relatively fast to make a response. The second, more intriguing, mechanism is a fast-acting process that has been likened to a spread of activation within an interrelated network (see **Figure 5**). This second mechanism presumably acts independently of the subjects' conscious processing and appears in situations where the prime is presented so briefly that subjects are unaware of its presence. Interestingly, Balota and Lorch (1986) found priming between words that on the surface do not appear to be directly related (e.g., *lion-stripes*). This is predicted by the spreading activation network perspective, because hidden within the presumed semantic network are mediating nodes (e.g., in this case *tiger*). In this way, researchers use the priming technique to make inferences about the representation of knowledge in the lexicon, and the processes used to access that information (see Hutchison, 2003 for a recent review).

Figure 5 Collins and Loftus's (1975) spreading activation model network. Copyright (1975) by the American Psychological Association. Reproduced with permission.

In addition to single-word contexts, there have been many studies investigating the influence of sentence context on word recognition latencies (see, for example, Stanovich & West, 1983). One of the intriguing initial findings in this area is that sentence context does not influence lexical processing immediately but has an influence later on in integrating the word with the context. For example, Swinney (1979) found similar levels of activation, as reflected by priming techniques, for the interpretation of *bug* referring to *spy device* and *insect*, even though the word *bug* was immediately preceded by "spiders, roaches, and other" as part of a sentence context. It is only later on in processing that the sentence context disambiguates the word. Thus, it was argued that early lexical processes proceed relatively uninfluenced by sentence context, akin to the mechanism of automatic spreading activation mentioned above. This work was particularly important in advocating a dedicated self-encapsulated lexical module (e.g., Fodor, 1984). More recent work on this topic suggests that context can have an early influence if it is sufficiently strong (see Tabossi and Sbisa, 2001 for a review).

Word Recognition: the Future

The study of visual word recognition will continue to be a vital area of research in experimental psychology and psycholinguistics, with a number of important challenges. For example, we believe that future models will take into consideration the manner in which attention and task constraints influence the lexical processing system. As one can see from the models described above, most models assume a relatively passive lexical system that responds to stimulus input. However, a more comprehensive model will most likely include an attentional system that modulates the weights on specific pathways depending upon the goals of a given task. In addition, there will be some constraints provided from the *in vivo* studies of the human brain while it is engaged in lexical processing, via neuroimaging techniques. As noted above, multiple models may be able to accommodate the same set of findings. It is likely that understanding patterns of neural activity in circumscribed brain areas will provide an important next step in this literature (e.g., Binder *et al.*, 2003).

Word Stress

H van der Hulst, University of Connecticut, Storrs, CT, USA

© 2006 Elsevier Ltd. All rights reserved.

The Basic Phenomenon

Consider the English word *hippopotamus*. Almost every speaker of English will pronounce the medial syllable of this word with more 'articulatory force' than all other syllables. It is common to refer to this syllable as being *stressed*, or carrying *stress*. Dictionaries often signal the location of word stress using a dash or 'accent mark' (hippo'potamus) before the stressed syllable, or sometimes they use capitalization (hippoPOtamus). Phonetically, 'articulatory force' involves a number of properties that the stressed syllable has to a greater degree relative to the unstressed syllables. For example, the stressed syllable is more precisely articulated, longer, louder, and often higher pitched. Duration, loudness, and pitch are all properties that all syllables have to some degree, but the stressed syllable has all of these to the greatest degree. In addition, its consonants and vowel may have special allophonic properties such as aspiration or 'full quality' (as opposed to being reduced). All these phenomena can be observed in our example, which might be transcribed phonetically as follows: [hIpəp^{h}arəməs]. The /p/ of the medial syllable is aspirated, unlike the /p/ of the second syllable. The second, fourth, and fifth vowel is [ə], the schwa, a vowel that never occurs in a stressed syllable, where we always find the full vowel quality; the occurrence of the vowel [I] in the first syllable will be discussed below. Besides phonetic and allophonic cues, stress also has phonotactic cues in that stressed syllables often allow more phoneme combinations (like more complex onset clusters, or more complex nuclei).

From Stress to Accent: Cues for Accent

While many languages display the phenomenon of word stress (the percentage of languages is not known) as just described, many other languages display a quite similar phenomenon in that a particular syllable in the word is singled out, the difference being that the cues for its special status are not the same phonetic, allophonic, and phonotactic cues that we find in English. In one specific case that is often mentioned, the syllable that stands out is mainly or perhaps exclusively associated with a high(er) pitch. The typical example is (Tokyo) Japanese in which words have pitch patterns that involve a high pitch on what is called the *accented* syllable (in addition, there is leftward spreading of this high pitch); McCawley (1968), Haraguchi (1977). Hyman (1977) referred to such systems as 'pitch-accent systems,' while proposing to use the term 'stress-accent systems' for cases like English. In this terminological proposal, the term 'accent' refers to the property of 'standing out,' while the terms 'stress' and 'pitch' refer to the phonetic cues that signal the location of the accented syllable. It is conceivable that a fine-grained typology of cues for word accent will reveal many more types such as duration-accent systems (in which duration is the primary or only cue). It would seem that in such a typology, the term 'stress' refers to a rather heterogeneous collection of phonetic, allophonic, and phonotactic properties. It may be that such a collection of properties represents a true type, but it may also be that, on closer investigation, so-called pitch-accent languages may also involve additional allophonic and phonotactic cues. In short, accent may be signaled in terms of many combinations of cues of various sorts. The cross-linguistic array of accentual cues is at present far from understood and much detailed phonetic and phonological analysis is needed in this respect; cf. Dogil and Williams (1999). The important point here is that it seems useful to separate the notion accent (a formal property of syllables without any link to specific cues) and accentual cue(s). In this article, the main attention will be on the notion of accent. Before embarking on a formal characterization of this notion, it must be pointed out that it is by no means necessary (given the above) that accents manifest themselves by cues in all cases. Of course, a discussion of accent in a language that apparently lacks any cue is pointless, but we must reckon with situations in which accents manifest their presence in specific circumstances or in specific ways in a language. As already indicated, in the absence of phonetic cues such as extra duration, loudness, etc., allophonic or phonological phenomena may designate a syllable as being accented. Also, it could be that in languages that have lexical tones (so-called lexical tone languages, which are often placed in opposition to accentual languages), distributional restrictions on tonal patterns may be accountable in terms of a distinction between accented and unaccented syllables. It has, in fact, been recognized that it is sometimes difficult to draw the line between tone languages with certain distributional restrictions and pitch-accent languages, the term tonal accent language being put forward as a label for the intermediate categories (cf. van der Hulst, 1999a, Sect. 1.5).

Functions of Word Accent

Intonation

Turning back to English, let us note a thus far ignored cue for word accent. Consider the example *hippopotamus* in the following sentence:

```
H                                H
|                                |
I have always wanted to be a hippopotamus
```

The 'H' symbols represent some of the units that make up the so-called intonational melody; in a full account, other tones will be specified (*see* **Intonation**). In English, speakers can draw the listener's attention to specific parts of the utterance (among other means) by associating high tones to certain words. The point here is to see (or hear) that these tones are associated with specific syllables in those words, namely the accented syllables. Thus, we see that intonational tones can be cues of word accent in the sense that these tones tell us which syllables in a word that carry them are accented. If we place *hippopotamus* in a sentence in which the speaker does not draw attention to it (because it has already been mentioned before), an H tone no longer signals the accent, which is now only cued by the other properties (in fact, it may be that pitch is not significantly among those, the claim that pitch is a relevant cue mainly being based on cases in which words carry an intonational tone). Intonational tones have been called 'pitch accents,' which can lead to some confusion with the notion of pitch accent that was used above with reference to pitch-accent systems (such as Japanese). The point is that word accent can be signaled by non-intonational pitch property at the word level, as in a pitch accent language, or, as in English, by an intonational pitch property. In both cases, we deal with a pitch property that associates with an accented syllable, at the lexical level (Japanese) and postlexical level (English).

The role that accents play in the anchoring of intonational tones can be understood both as providing a cue for word accent, but also as a function of word accents, given that a system must be in place for anchoring the intonational units to the 'text.' Conceivably, other anchoring systems could be, and probably have been adopted, for example those in which intonational units consistently associated with the first or last syllable in phrases, irrespective of the location of word accents.

Demarcation

It has also often been suggested that word accents function as parsing cues, the idea being that listeners can use knowledge of accent location to cut up sentences into words. This has been called the demarcative function of word accent. If the location of accent is consistently on the first syllable, listeners know that every accent marks the beginning of a new word. From this perspective, it is expected that word accents always occur on word edges, i.e., on the first or last syllable, but this is not the case. As we will see below, word accents can occur on nonedge syllables, either consistently (in which case their location can still be a useful cue for finding word edges by making the relevant computations), or nonconsistently (for example, when syllable weight plays a role; cf. below). We will learn that some of the nonconsistent cases can no longer be said to have a demarcative function.

Rhythm

Speech depends on sequential motoric behavior involving repetitions of units such as syllables, words, and phrases. It seems to be that human bodies (and human minds) function best when sequential motoric behavior is carried out 'rhythmically,' i.e., in terms of alternating 'stronger' and 'weaker' actions that are spaced out fairly regularly. Thus, sequences of syllables might display a strong-weak pattern. Let the string in (1) be a sequence of words (delimited by square brackets) in which the sigma symbols represent syllables. At level 1, each word has been rhythmically organized into strong (indicated by 'x') and weak syllables. With several level 1 x-marks being present in longer words, we expect to find a further rhythmic grouping within words of strong syllables (level 2). To keep the structure consistent, we will also assign a level 2 x-mark in shorter words that have only one level 1 x-mark.) Each word now has a perfect rhythmic structure. Note that the specific form of this rhythmic structure might be different depending on how in particular we distribute the level 1 marks, i.e., whether we start on the left or right side of the word, or whether we start on the syllable at the (left or right) edge or first skip one syllable. Below we will see that such choices are real in that languages may display different types of rhythm.

Now we encounter a sequence of words forming phrases (indicated by '(. . .)'). To be in rhythmic alternation, words must have a designated syllable that functions as the anchor of strong beats within the phrasal domain. Let us say that this is the rightmost strong syllable in the word at level 2, but this could again be different in that we could have picked the first strong syllable at this level. Having now created level 3 (the so-called primary word accent), we are in a position to assign a rhythmic structure to the sequence of words that form a phrase. Let us say that

each last word, and every other preceding word, in the phrase must be rhythmically strong; this gives us level 4. Finally, we may rhythmically group the phrases that form the sentence (indicated by '{. . .}') and for this it is necessary that multiword-phrases have a potential anchor point for rhythmic beats. Let us say that in our hypothetical example, this is always the last word in the phrase (level 5, 'the phrasal accent'). At level 6, we represent the rhythmic alternation of phrases (ignoring a potential cyclical procedure enforced by any subgrouping of phrases within the sentence, or, for that matter the question of whether the sentence as a whole has a strongest beat, the so-called sentence accent, which would then be level 7). It should be clear that the x marks at level 3 and 5 are necessary in order to allow a rhythmic grouping of words and phrases. These x's represent word accents and phrase accents, respectively.

(1)

metrical tree. We will see in a moment that the metrical tree, as traditionally understood **incorporates** a grid structure so that, in the end, only one structure is needed.

Trees primarily express the notion of constituency or grouping. Terminal elements are grouped into constituents and these constituents are then grouped into successively larger groupings. In linguistics, the left-right order of symbols (imposed by the two-dimensional graphic display) is usually interpreted as expressing the left-right order of the linguistic units that they stand for. A third piece of information can be expressed by trees, namely the fact that in each grouping one element has a special status; this element is called the head, the other element(s) being called dependent(s). Metrical phonology (or, as it is often called, prosodic phonology) offers a theory of phonological grouping that incorporates the idea of headedness. The specific structures that are advanced exhibit mostly binary branching nodes as well as strict layering (rather than recursion) of constituent types (such as syllables, feet, prosodic words, etc.). The idea of headedness in phonological grouping has also been the cornerstone of Dependency Phonology (*see* **Dependency Phonology**) and its relevance to stress has also been proposed by Rischel (1972).

Within the domain of words, phonological grouping starts with segments that form syllables (and possibly subsyllabic units such as onsets and rhyme and/or moras). The novelty of metrical theory and Dependency Phonology lies in the proposal that the grouping of syllables into headed, binary constituents (called feet), can be used to express rhythmic alternation in the sequence of syllables. A further grouping of feet can then be used to express word accent:

The notation adopted here is the one proposed in Dependency Phonology. We also find it in Hammond (1984) within the metrical model. Each unit that is a head is dominated by a vertical line and a small circle. Metrical phonology originally used the labels 'S' for head and 'W' for dependent. It is obvious that the little circles, if taken in isolation, represent the exact same structure as the grid structure in (1) (cf. Ewen, 1986).

The organization of feet into words has been subject to some debate. In (2), the first two feet form a 'superfoot' (or cola). This structure clearly expresses that the first syllable is more prominent than the third. An alternative would be to group feet into uniformly branching trees only:

Independent of this issue, others have proposed disregarding the level between the foot and the word. Halle and Vergnaud (1987), who adopt a bracketing notation for tree structure, adopt this view (using the grid-like x symbols to represent headedness):

This bracketing approach has been further developed in Idsardi (1992) with an interesting twist. Idsardi suggests that structure can be built up by rules that insert isolated left or right brackets (forming what one might call open constituents). Apart from providing highly economical algorithms, it might be that such open constituents are useful devices in cases where we deal with metrical incorporation (of 'stray syllables' or clitics; cf. 'Unbounded Systems'). Pushed further, Idsardi's approach might lead to a theory in which the symbols (the brackets) function more like boundary symbols than graphic devices for tree structures (cf. van der Hulst).

The claim that phonological constituents are headed provides a formal reconstruction for the notion accent: being accented can now be understood as being a head. In that sense, it may be that the 'function of accent' is identical to the function of heads, which is perhaps a purely cognitive function, i.e., a necessary property of mental representations of a certain type. If such a view can be defended, it follows that all languages must necessarily be accentual, even those that lack accentual cues. Accentual cues would exist as parasitic (and potentially useful) devices to a structure that exists for independent, cognitive reasons.

A Parametric Theory of Accent

If the accentual pattern of *Apalachicola* is anywhere near representative of accentual word patterns of English words, we might conclude that the following two statements characterize English word accent:

(5) The feet are left-headed (i.e., trochaic)
The word is right-headed (the rightmost foot is the head foot)

Together these two statements characterize a penultimate (paroxytone) accent on the assumption that syllables are grouped into feet from right-to-left, i.e., starting at the end of the word. That direction of footing matters becomes evident when we consider a word with an odd number of syllables:

(6)

To achieve penultimate accent, a left-headed foot must span the two rightmost syllables, a result that would not be obtained if grouping proceeded from left-to-right:

(7)

Unfortunately, for English, we cannot always assume that feet are formed throughout the word from right to left. A consistent application of this procedure would yield:

(8)

But the second syllable of this word bears no accent, witnessed by its schwa-vowel. Here we find a first indication that generalizations concerning primary accent and nonprimary accent may not be expressable straightforwardly in a single set of statements. It would seem that something like (9) is required:

(9) Form one right-headed foot at the right edge
Form right-headed feet from left to right avoiding clash
The word is right-headed

(10)

The medial syllable that thus far remains unfooted could now be incorporated by convention into the first foot, forming a (derived) ternary foot, assuming that metrification must be exhaustive:

(11)

Below, we will see that a full statement of English word accent requires additional statements (bearing on the role of syllable weight). However, (5) would do quite well for almost all words in Polish where weight effects are missing. Let us now investigate how other types of word accent can be accounted for.

Languages display a rich variety of accentual types and although many matters are still unclear or unsettled, accent typology forms a quite well-developed and highly interesting area of phonology. Many questions that remain involve the character and formal representation of nonprimary accents. Here, let us focus first on primary accent locations. In many languages, primary accent locations are fixed on a specific syllable for the vocabulary as a whole (barring exceptions that may always occur):

(12) Initial accent: Icelandic, Hungarian
Second syllable accent: Dakota
Third syllable accent: ?
Antepenultimate accent: Macedonian
Penultimate accent: Polish
Final accent: Turkish

A rich source of information about these and many other accentual systems, containing references and many detailed analyses, remains Hayes (1995). It would seem that five locations occur, third syllable accent being attested in one questionable case (Winnebago). But there are significant frequency differences in, as far as we can tell, the present databases:

(13) $[\sigma\ \sigma \ldots \sigma\ \sigma\ \sigma]$

Penultimate and initial location are favored over final location, second syllable and antepenultimate accent being rare (cf. Hyman, 1977). It is easy to see how initial accent can be derived. We simply form a left-headed foot at the left-edge of the word and make sure that the word is left-headed. But how do we derive second syllable and final accent? Hayes (1980) adopted the idea that such systems involve right-headed (or iambic) feet. Clearly, a right-headed initial foot delivers second syllable accent, while a right-headed final foot delivers final accent (provided that in both cases these feet are heads of the word). We now have the rudiments of a parametric theory of word accent:

(14) Accentual parameters (for primary accent)
Foot type: left-headed/right-headed
Edge: left/right
Word type: left-headed/right-headed

In fact, the parameters Edge and Word type could be considered one and the same if we simply assume, as suggested above, that separate statements are made about primary and nonprimary accents and that, by convention, primary accent feet are heads of words. Thus for English, we might then state:

(15)

Primary accent	Nonprimary accent
Foot type: left-headed	Foot-type: left-headed
Edge: right	Edge: left

In this view, as a matter of convention, foot formation for primary accent is noniterative, while foot formation for nonprimary accent (i.e., rhythm) is iterative. It remains to be seen whether, perhaps, the foot type for rhythm is always identical to the foot type for primary accent, or, alternatively, whether the foot type for rhythm is universally trochaic.

Standard metrical theory did not adopt the idea of separating primary and nonprimary accent. This model adopted a procedure that would first construct a layer of feet across the whole word, while then 'promoting' a left or right peripheral foot to head status of the word. Under this approach, differences between generalizations concerning primary and nonprimary accent would necessitate the formulation of adjustment rules of various kinds. The idea to separate primary and nonprimary accent was suggested in van der Hulst (1984) and developed in subsequent work (van der Hulst, 1996, 1997, 1999a, 1999b). Others (within metrical or other frameworks) have made similar suggestions (Roca, 1986; Hurch, 1992; Harms, 1981). In an approach that separates both phenomena, it must be stated that primary accents are not only more prominent than secondary accents, but also that they literally take precedence over secondary accents in that the latter fill out the accentual space that is left open by the primary accent foot, while paying respect to the primary accent location by avoiding clash. Such 'top-down' effects are inexpressible in a procedural bottom-up standard metrical account, which is incompatible with the idea that primary accent is somehow assigned first or somehow takes precedence. In Optimality Theory, this fact has been taken as an argument to adopt a nonprocedural constraint-based approach, which allows constraints bearing on head feet (primary accent) to outrank constraints bearing on dependent feet (nonprimary accents). Alternatively, it might be argued that primary accent and nonprimary accents are constructed in different planes, or that primary accent assignment and assignment of rhythmic structure are fully complementary (cf. van der Hulst (1996), for this latter approach).

Further Issues

Extrametricality

In the preceding discussion, we have ignored the case of Macedonian in which accent regularly falls on the antepenultimate syllable. Little of interest has been said about how to handle such cases. It is apparently the case that the rightmost syllable of words can be 'ignored' when metrical structure is constructed. Hence, this syllable is said to be extrametrical. This is a parametric option that, apparently, is limited to the rightedge, hence the absence of third syllable accent. An extrametrical syllable can be incorporated into the rightmost foot if metrification of words must be exhaustive. Technically speaking, we could now reconsider penultimate systems as involving extrametricality and iambic feet, but little would be gained by such a move, especially in light of the view that trochaic grouping seems to be the preferred type (witnessed by the preference of initial over second syllable accent, and by the predominance of trochaic patterning of nonprimary accents).

Exceptions

Even in Polish, some words may exceptionally have either final or antepenultimate accent. The latter can be accounted for by assuming that extrametricality may be lexically marked in such cases (rather than following from a parametric setting). Final accent also requires a lexical mark. It has been suggested that such cases can be handled by lexically 'specifying' a silent syllable. This has been called catalexis by Paul Kiparsky (cf. Kager, 1995 for discussion). Alternatively, the final syllable can be marked as a head, using a diacritic mark. The marking device is preferable if we find that left-edge systems (with fixed initial or second syllable accent) also can have exceptions, such as a second syllable accent in an initial system. If extrametricality is not available as a left-edge device, only marking could do the job. In the reverse case of first syllable accent in a second syllable system, only marking could be used even if extrametricality would be adopted at the left-edge. Below, it is suggested that the head marking option is also preferable for other reasons.

It has been argued that languages can have so much lexical marking that the suggestion that accent is fixed loses its meaning. It has been suggested that such cases should be referred to as free accent, and it has sometimes been implied that in such systems accent can be anywhere in the word, i.e., in locations other than those in (13). Such claims must be looked at with skepticism. Excluding consideration of so-called unbounded accent systems (cf. 'Foot Typology'), exceptions, even when highly frequent, are restricted by occurring within the left- or right-edge two-syllable window (modulo extrametricality). In Spanish, for example, accents may occur in the final, penultimate or antepenultimate syllable and (excluding the effects of morphology, cf. 'Unbounded Systems') lexical marking is required to derive two of these three options (cf. Roca, 1999 for a comprehensive account).

It seems, furthermore, likely that the occurrence of exceptions is also restricted in that exceptions do not

seem to occur on the opposite edge of where regular accents occur, or, if the notion 'regular' is not applicable, that accents are located on opposite edges within the same language. To the extent that such mixes occur, we would expect that the languages in question have mixed vocabularies with words that originate from other languages, while maintaining different phonological systems for these lexical strata. In that case, one would have different accentual accounts of the two cases and there would be no exceptions in the true sense of the word.

Variable Weight

We have so far considered cases in which accent is fixed on a specific syllable in all words (barring exceptions and free accent systems). Many languages have accentual systems like that. Many others display the effect of syllable weight (cf. Hyman, 1984; Goedemans, 1996, 1999). Here is an example:

(16) Accent falls on the final syllable if it is closed, otherwise on the penultimate syllable

Even though accent placement is predictable by rule, accent location is not fixed. Rather it varies due to the influence of the content of the syllables within the accentual window. In a system of this type, closed syllables are said to attract accent. The regular foot type is trochaic but there is a constraint that bars closed syllables from being the dependent member in a foot, or stated positively, that requires heavy syllables to be heads. In a parametric view, this constraint would be parametrically present or absent in the grammar. If present, the system is called weight-sensitive.

It is easy to understand what is going on in weight-sensitive systems. Accent can be understood as 'positional prominence', i.e., as prominence due to position with reference to a word edge. A syllable is assigned head status simply for being in the right position in the word. But syllables are not all equal in terms of their phonological content. Arguably, closed syllables have more content. If a language has closed syllables (some do not), and there is an accentual system, a potential conflict arises when a syllable that is prominent due to content is placed in a position that is positionally nonprominent. This is exactly what happens if a final heavy syllable is left unaccented, while the penultimate syllable (whether heavy or light) is accented. If the weight constraint is active in a language (or high ranked in an Optimality Theoretic account), final heavy syllables will form the head of a (nonbranching) foot, which, as the rightmost foot, can then end up as the head foot of the word.

What makes syllables heavy can differ from language to language, or several factors may be at play in a single language. Typical weight factors are syllable closure and vowel length. In some cases, the type of consonant that closes the syllable may be critical such that only closing sonorant consonants make the syllable heavy. Other factors are full vowel quality as opposed to reduced vowel quality, or having a lexical high tone. It may even be the case that vowel height (or vowel sonority) plays a role, with open (more sonorous) vowels attracting accent. Typically, there are just two weight classes (heavy and light), but it has been argued that in systems where segmental sonority is a factor, more than two weight classes may be distinguished. In such cases, the weight constraint cannot absolutely bar certain syllable types from dependent position. Rather, a constraint must be postulated that prevents the dependent syllable from being heavier than the head syllable. (The more typical binary weight systems are simply a special case of this more general 'mismatch' constraint).

English word accent is clearly weight-sensitive (in addition to being governed by a substantial number of lexical exceptions); cf. Kager (1989) for a detailed treatment.

Returning now to the phenomenon of lexical exceptions, one might suggest that syllables that must be marked as heads (such as final accented syllables in Polish) display what might be called diacritic weight. Thus, by using marking (rather than catalexis), a uniform account is possible of certain types of exceptions and accent placement that is sensitive to phonological weight.

Foot Typology

In accordance with the foot parameters in (14), we could have four foot types. Hayes (1980) provides examples for all of them in both directions of footing, thus revealing eight types of languages. Subsequent research has revealed, however, that not all types are widely attested. Hayes (1995) reports that systems making use of the weight-insensitive iamb and the weight-sensitive trochee are suspiciously rare, or, worse, produce unattested patterns under certain circumstances (i.e., in interaction with other parameter settings). Hayes therefore proposes to eliminate the weight-insensitive iamb and to replace the weight-sensitive trochee by a so-called moraic trochee. A moraic trochee is a left-headed foot type that maximally contains two light (i.e., monomoraic) syllables or one heavy (i.e., bimoraic) syllable.

The cases that were represented in earlier works with weight-insensitive iambs and the weight-sensitive trochees were now in need of an alternative analysis. By allowing certain manipulations at the edges of accentual domains (like excluding syllables from the parse by extrametricality) or postulating

empty final syllables (catalexis), such an alternative could usually be found.

The possibility of making these reanalyses showed that the standard theory was overly rich anyway. The reanalyses of course had to express the same prominence patterns but usually led to different constituent structures when compared to the original analyses. Even though details of foot structure may in principle play a role in the application of segmental phonological rules, such evidence requires access to details of the phonology that were often not studied or reported in grammars or phonological sketches.

The next step was taken by Kager (1993) who extended the bimoraic upper bound of moraic trochees in two ways. Firstly, he proposed that weight-sensitive iambic systems do not require (lh) feet. He suggested reanalyses for the few cases that were originally analyzed with such feet. Secondly, Kager suggested that the bimoraic requirement was also the lower bound, which implies that so-called monomoraic (also 'unary' or 'degenerate') feet were banned. Hayes (1995) accepts Kager's ban on monomoraic feet with certain qualifications that I will not discuss here.

Van de Vijver (1997) and van der Hulst (1999b) question the existence of iambic feet in more radical terms, both arguing for different ways of dealing with 'iambic' systems. For extensive discussions of these developments see van der Hulst (1999a, 1999b, 2000).

Unbounded Systems

In all systems discussed so far, accent placement results from the formation of a foot at the right or left edge of the word. A different type of system exists in which accent placement is purely driven by syllable weight without foot formation. Four basic types occur:

(17a) Last/First: accent to last heavy syllable and, if there is no heavy syllable, the first syllable
(17b) Last/Last: accent to last heavy syllable and, if there is no heavy syllable, the last syllable
(17c) First/Last: accent to first heavy syllable and, if there is no heavy syllable, the last syllable
(17d) First/First: accent to first heavy syllable and, if there is no heavy syllable, the first syllable

Various approaches to such systems, called 'unbounded,' can be found. The classical metrical account relies on unbounded weight-sensitive feet. Prince (1985) suggested an account with bounded feet that directly target heavy syllables rather than being assigned proceeding from a word edge. The fact that such systems do not appear to have rhythmic, nonprimary accents (although more detailed descriptions are needed), as well as the fact that primary accents can be located anywhere in the word (dependent on where heavy syllables occur) suggest that such systems do not rely on binary feet. Hayes (1995) indeed suggests that these systems are not rhythm-based.

A different procedure is suggested in van der Hulst (1996, 1999a) where it is argued that the four options in (17), in fact, also occur in bounded systems, albeit within a two-syllable window (reminiscent of peripheral foot formation). The proper treatment of such systems remains an open issue.

Relevance of Morphological Structure

What is the domain of word accentual structure? So far we have assumed that there is a clearly defined notion of 'word' that constitutes this domain. But in some cases, it appears that the domain of word accent is smaller than the word **taken as the maximal morphological and minimal syntactic construct**, while in other cases it seems to be bigger. The parts that make up compounds in English clearly form separate domains for word accent. As such, English compounds require separate statements for selecting a word accent from the word accents of its members. Word accents that are not thus selected survive in the accentual structure of compounds as nonprimary accents. Embedded units of derived words have also been argued to form separate accentual domains, the idea being that the accentual procedure first applies to the most embedded unit and then successively applies to the larger domains that are formed by the addition of affixes. This procedure is called cyclical assignment of accent. Again accent of embedded cycles may survive as nonprimary accents of the whole word. The facts are less clear and the cyclical account of word accent in derived (noncompound) words (as proposed in Chomsky and Halle, 1968) is debatable. Predicted cyclic nonprimary accents do not always show up where they are supposed to.

Cases of this sort suggest that the domain of accent, if it is to be called 'a word,' cannot be the morphosyntactic word. Students of accent and phonological constituent structure have introduced the notion prosodic word for this purpose. A prosodic word is thus a grouping of feet that may coincide with substructure of the morphosyntactic word. It appears to be necessary to regard the prosodic words as a recursive unit in those cases where we find multiple affixation (assuming the validity of a cyclic account). It remains an open question whether compounds form prosodic words that themselves consist of prosodic words.

Morphology can also be relevant in unbounded systems. In Russian, where morphemes have unpredictable ('free') accent locations, polymorphemic

words need a statement to indicate which accent wins if there is more than one, or to indicate an accent location if no morpheme is lexically accented. The relevant statement is that in (17a) with 'heavy' replaced by 'lexically accented.'

Much is still unknown or unclear concerning the relevance of morphological structure to accent placement, especially in language of the 'polysynthetic' type in which we find words composed of many morphemes; cf. Revithiadou (1998).

In those cases where accent placement has been argued to refer to domains larger than the morphosyntactic words, we also need to distinguish several types of cases. Much depends on one's treatment of inflection which, if dealt with syntactically, may necessitate application of (special) accentual rules to inflected words. Another issue concerns so-called clitics (*see* **Clitics**), which, understood as separate syntactic units, may lack word accent and incorporate into the metrical structure of a preceding or following word, with possible effect on the accentual structure of the resulting clitic group (which some regard as an extended version of the prosodic word); cf. Peperkamp (1997).

A further sense in which word accent may refer, or be dependent on larger domains, concerns the phenomenon of accentual shift in phrasal combinations. In English, for example, many adjectival words occur with different accentual structures depending on whether they are placed before a noun or not. The word *thirteen* is finally accented in isolation or in final positions in phrases, but appears to have initial stress in:

(18) thirteen men

If the final pattern is taken to be basic, a phrasal adjustment is required (often called the rhythm rule). In any event, word accent seems dependent on phrasal context. There is a rich literature on this topic (Prince, 1993; Selkirk, 1984; Giegerich, 1986; Visch, 1999; Hayes, 1994; Gussenhoven, 1991).

Optimality Theory

The bloom of metrical theory occurred throughout the 1980s. With the rise of Optimality theory in the early 1990s, (OT) we see an initial focus on some areas where OT appears to offer an advantage, followed by other work in which all the early generalizations are translated from parametric accounts into accounts based on constraint-ranking, often with no obvious gain or loss. The arena of accentual phenomena seems to display quite a few cases where constraint-ranking is appealing. We already mentioned the interplay between primary and nonprimary accent, which is problematic for a bottom-up procedural account (although an alternative approach was suggested). In the case of syllable weight, we also seem to see the effect of a conflict between positional prominence and prominence due to content. To say that weight-sensitive languages rank weight-sensitivity over some other constraint that demands 'regular rhythmic grouping' seems appealing, but, of course, an account that appeals to presence or absence of the weight constraint in the grammar works equally well. In fact, it is quite easy to restate all parametric work in terms of ranked constraints, since, from a formal point of view, the power of parametric accounts is included within the power of OT accounts.

Although useful new empirical work has been carried out within the OT area of some specific accentual systems (Hung, 1993), in general, there has been much less advancement of our understanding of word accentual typology and accentual representations in the 1990s than in the previous decade. Of course, it is to be expected that OT analyses, with their virtually limitless introduction of new constraints, apparently can deal with subtle or 'gradient' phenomena that fall outside the reach of the 'cruder' parametric approaches. It remains to be seen, however, whether such subtle or gradient phenomena, which must ultimately be dealt with, necessarily require the powerful apparatus offered by OT.

Conclusions

This article has dealt with word accent, both in terms of the factors that constitute this phenomenon at the descriptive level and in terms of the theoretical apparatus that has been proposed to represent it in formal terms. The study of word accent (a term that is preferred over word stress; cf. 'From Stress to Accent: Cues for Accent') forms a rich area of phonological theoretical and typological research that continues to inspire the formulation of new approaches and is thus in the forefront of the continuing development of phonological theory.

The Princeton WordNet

Background and Motivation

WordNet, a manually constructed electronic lexical database for English, was conceived in 1986 at Princeton University, where it continues to be developed. Experiments by researchers in Artificial Intelligence (Collins and Quillian, 1968, inter alia) probing human semantic memory inspired the psycholinguist George A. Miller to test the underlying theories on a large scale.

Design and Contents

WordNet is a large semantic network interlinking words and groups of words by means of lexical and conceptual relations represented by labeled arcs. WordNet's building blocks are synonym sets (synsets), unordered sets of cognitively synonymous words and phrases (Cruse, 1986). Each member of a given synset expresses the same concept, though not all synset members are interchangeable in all contexts. Examples are {*car, automobile*}, {*hit, strike*}, and {*big, large*}. All synsets further contain a brief definition, and most include one or more sentences illustrating the synonyms' usage. A domain label (*sports, medicine, biology*) marks many synsets.

Joint membership of words in a given synset illustrates the phenomenon of synonymy. Membership of a word in multiple synonyms reflects that word's polysemy, or multiplicity of meaning. Thus, *trunk* appears in WordNet in several different synsets, including {*trunk, tree trunk*}, {*trunk, torso*}, and {*trunk, proboscis*}.

Coverage

WordNet consists of four separate components, each containing synsets with words from the major, open-class, syntactic categories: nouns, verbs, adjectives, and adverbs. WordNet 2.1 contains almost 118 000 synsets, comprising more than 81,000 noun synsets, 13 600 verb synsets, 19 000 adjective synsets, and 3 600 adverb synsets.

Relations

Synonymy is the major lexical relation among individual word forms; another is antonymy, as between the pairs {*wet*} and {*dry*} and {*rise*} and {*fall*}. Morpho-semantic relations link words from all four parts of speech that are both morphologically and semantically related (Fellbaum and Miller, 2003). For example, the semantically related senses of *interrogation,*

The Princeton WordNet

Background and Motivation

WordNet, a manually constructed electronic lexical database for English, was conceived in 1986 at Princeton University, where it continues to be developed. Experiments by researchers in Artificial Intelligence (Collins and Quillian, 1968, inter alia) probing human semantic memory inspired the psycholinguist George A. Miller to test the underlying theories on a large scale.

Design and Contents

WordNet is a large semantic network interlinking words and groups of words by means of lexical and conceptual relations represented by labeled arcs. WordNet's building blocks are synonym sets (synsets), unordered sets of cognitively synonymous words and phrases (Cruse, 1986). Each member of a given synset expresses the same concept, though not all synset members are interchangeable in all contexts. Examples are {*car, automobile*}, {*hit, strike*}, and {*big, large*}. All synsets further contain a brief definition, and most include one or more sentences illustrating the synonyms' usage. A domain label (*sports, medicine, biology*) marks many synsets.

Joint membership of words in a given synset illustrates the phenomenon of synonymy. Membership of a word in multiple synonyms reflects that word's polysemy, or multiplicity of meaning. Thus, *trunk* appears in WordNet in several different synsets, including {*trunk, tree trunk*}, {*trunk, torso*}, and {*trunk, proboscis*}.

Coverage

WordNet consists of four separate components, each containing synsets with words from the major, open-class, syntactic categories: nouns, verbs, adjectives, and adverbs. WordNet 2.1 contains almost 118 000 synsets, comprising more than 81,000 noun synsets, 13 600 verb synsets, 19 000 adjective synsets, and 3 600 adverb synsets.

Relations

Synonymy is the major lexical relation among individual word forms; another is antonymy, as between the pairs {*wet*} and {*dry*} and {*rise*} and {*fall*}. Morpho-semantic relations link words from all four parts of speech that are both morphologically and semantically related (Fellbaum and Miller, 2003). For example, the semantically related senses of *interrogation,*

interrogator, interrogate, and *interrogative* are interlinked. Conceptual-semantic relations link not just single word forms but entire synsets.

Nouns in WordNet

Hyponymy

Concepts expressed by nouns are densely interconnected by the hyponymy relation (or hyperonymy, or subsumption, or the *ISA* relation), which links specific concepts to more general ones. For example, the synset {*mailbox, letterbox*} is a hyponym, or subordinate, of {*box*}, which in turn is a hyponym of {*container*}. {*Mailbox, letter box*} is a hypernym, or superordinate, of {*pillar box*}, which denotes a specific type of mailbox. Hyponymy builds hierarchical 'trees' with increasingly specific 'leaf' concepts growing from an abstract 'root.' All noun synsets ultimately descend from {*entity*}. (See Figure 1.)

Types vs. instances Among the concepts represented by nouns, WordNet distinguishes types and instances. Common nouns are types: *tree* is a type of *plant*, *china* is a type of *crockery*. Proper names are instances: *China* is an instance, rather than a type of a *country* (Miller and Hristea, 2004).

Meronymy

Another major relation among noun synsets is meronymy, which links synsets denoting parts, components, or members to synsets denoting the whole. Thus, {*finger*} is a meronym of {*hand*}, which in turn is a meronym of {*arm*}, and so forth. Meronymy in WordNet actually encompasses three distinct part-whole relations. One holds among proper parts or components, such as {*leg*} and {*table*}. Another links substances that are constituents of other substances: {*oxygen*} is a part of {*water*} and {*air*}. Members such as {*tree*} and {*parent*} are parts of groups such as {*forest*} and {*family*}.

Figure 1 A WordNet noun tree.

Verbs

Verbs are organized by a several entailment relations (Fellbaum and Miller, 1990; Fellbaum, 1998b). The most prevalent is troponymy, which relates synset pairs such that one expresses a particular manner of the other (e.g., {*whisper*}-{*talk*} and {*punch*}-{*strike*}) (Fellbaum, 2002). Like hyponymy, troponymy builds hierarchies of several levels of specificity. Other relations are backward entailment (*divorce-marry*), presupposition (*buy-pay*), and cause (*show-see*). (See Figure 2.)

Adjectives

WordNet distinguishes descriptive and relational adjectives. Descriptive adjectives are organized into direct antonym pairs, such as *wet-dry* and *long-short*. Each member of a direct antonym pair is associated with a number of 'semantically similar' adjectives. *Damp* and *drenched* are semantically similar to *wet*, and *arid* to *dry*. These concepts are said to be indirect antonyms of the direct antonym of their central members, i.e., *drenched* is an indirect antonym of *dry*, and *arid* is an indirect antonym of *wet* (Miller, 1998; Gross *et al*., 1989). (See Figure 3.)

Figure 2 A WordNet verb tree.

Relational adjectives (*atomic, nuclear*) are linked to the corresponding morphologically and semantically related nouns (*atom, nucleus*). Most adverbs point to their base adjectives (*rapid-rapidly, slow-slowly*).

Inheritance and Reversibility

Two important components of WordNet's design are inheritance and reversibility. Inheritance applies to hierarchy-building relations. If {*mailbox, letter box*} is encoded as a hyponym of {*box*}, and {*box*} as a hyponym of {*container*}, then {*mailbox, letter-box*} is automatically recorded as a hyponym of {*container*}, via the principle of inheritance. Similarly, if {*finger*} is a part of {*arm*}, and {*hand*} is part of {*arm*}, then {*finger*} is necessarily a part of {*arm*}, too. Many concepts are assigned to both types of hierarchy.

Relations are encoded in WordNet only once between a given pair of synsets or words. The pointer gets automatically reversed, so if {*tree*} is manually encoded as a meronym of {*forest*}, then {*forest*} will automatically become a holonym of {*tree*}. And if {*mailbox*} is manually encoded as hyponym of {*box*}, then {*box*} will automatically become a hypernym of {*mailbox*}. The lexical (word-word) relations are bidirectional, too.

WordNet as a Thesaurus

While paper dictionaries are necessarily organized orthographically, WordNet's structure centers upon a word's semantics. The digital format enables targeted look-up for meaning-related words and concepts from multiple access points. A browser with a pull-down menu lets the user search for a keyword's hyponyms, hypernyms, meronyms, antonyms, morphologically derived words, etc. Unlike a traditional thesaurus such as Roget's, the arcs among WordNet's words and synsets express a finite number of well-defined relations.

WordNet as a Tool for Disambiguation

WordNet's design has proved useful for a range of Natural Language Processing tasks that involve the challenge of word sense identification. While lexical polysemy can be resolved in part by statistical approaches, WordNet facilitates alternative or complementary symbolic approaches that exploit its encoding of semantic similarity. Given a polysemous word such as *trunk*, the information that its synonym

Figure 3 An adjective cluster in WordNet.

is either *tree trunk* or *torso* or *proboscis*, or that either *stem* or *body part* or *snout* are its superordinate, limits the possible readings to one.

Homonyms such as *trunk* have senses that are clearly distinguishable, but the dozens of senses of polysemous words such as *run* are less sharply differentiable, and the divergent entries in standard dictionaries indicate the impossibility of an agreed-upon sense inventory. WordNet's senses are no more fine-grained than those of a collegiate dictionary, but the requirements for disambiguation, rather than look-up of unfamiliar senses, highlight the constraints of an enumerative lexicon (Fellbaum *et al.*, 1997). Many contexts do not allow the singling out one of several overlapping senses. A solution, adopted by the Princeton WordNet and multilingual wordnets, is to group related senses together into one 'coarse' underspecified sense (Palmer *et al.*, 2005) for manual and automatic word sense identification.

Limitations of WordNet

WordNet is a lexical resource and as such does not contain any syntactic information. But there is strong evidence that, at least for verbs, semantic makeup and syntactic behavior are correlated (Levin, 1993). The extent to which WordNet's organization reflects syntactic classes is an independent test of this correlation (Kipper *et al.*, 2000). WordNet does not consider syntagmatic relations. Thematic and semantic roles of nouns functioning as arguments of specific verbs are not encoded, as in FrameNet (Fillmore *et al.*, 2003).

In 1986, digital corpora were not available, and WordNet's contents are largely derived from its creators' intuitions. More recently, the illustrative sentences have been based on web data. But WordNet, unlike some of its descendants, is not a corpus-induced dictionary.

Other Wordnets

Since the 1990s, wordnets are being built in other languages. EuroWordNet (Vossen, 1998) (EWN) encompasses eight languages, including non-Indo-European Estonian. EuroWordNet introduced some fundamental design changes that are the standard for subsequent wordnets. Other wordnets are linked to the Princeton WordNet.

The EuroWordNet Model (EWN)

Each wordnet relates to three language-neutral components: the Interlingual Lexical Index (ILI), the Domain Ontology, and the Top Concept Ontology. The Top Concept Ontology is a hierarchically organized set of about 1,000 language-independent core concepts expressed in all wordnets. The Domain Ontology consists of a set of topical concepts such as *traffic* and *illness*; unlike the domain labels in the Princeton WordNet, it is hierarchically structured. The ILI is an unstructured, flat list of lexical meanings consisting of a synset, an English gloss, and a reference to its source.

The language-specific wordnets consist of lexical items indexed to a set of synsets in that language. Each is related to a synset in the ILI, which functions as a language-independent ontology, or interlingua, that mediates among the synsets of the individual languages. To find equivalents across languages requires going through the ILI. Fine-grained ILI senses are clustered when necessary into coarser senses to allow unambiguous mapping to senses in other languages. The ILI includes a subset of Princeton WordNet's synsets plus concepts that are lexicalized in a given language where English shows a lexical gap. Thus, the ILI constitutes the superset of all concepts included in wordnets.

No relations link the ILI records, but the synsets in each language-specific wordnet are interconnected via independent semantic and lexical relations for each language. This design feature avoids the problem of crosslinguistic mismatches in the patterns of lexicalization and hierarchical structure.

In contrast to the Princeton WordNet's strict limitation to paradigmatic relations, connections in EWN are encoded among nouns and verbs that are syntagmatically associated, such as the pair *student* and *learn*. Another innovation is conjunctive and disjunctive relations. Conjunctive relations allow a synset to have multiple superordinates. Thus *knife* is both a kind of a *tool* and a kind of a *weapon*. This double parenthood captures the type vs. role (or function) distinction (Pustejovsky, 1995). Another example is *albino*, which can be a kind of *person*, *animal*, or *plant*. A disjunctive relation exists between *airplane* and its possible meronyms *propeller* and *jet*; a given type of airplane has either one, but not both, parts (Vossen, 1998).

As in the Princeton WordNet, words from different syntactic categories are linked when they are semantically and morphologically related, as are the corresponding senses of *visit* (verb), *visit* (noun), and *visitor*.

The wordnet web constitutes a powerful tool for multilingual Natural Language Processing (NLP) applications and crosslinguistic study of lexicalization patterns.

Global WordNets

Databases exist for 35 languages. Descriptions of many wordnet projects can be found in Singh (2002) and Sojka *et al.* (2004).

Wordnets for typologically adverse languages pose novel problems, especially with respect to the concept of *word*, which must be defined to determine synset membership. Challenges include the morphology of agglutinative languages such as Turkish and Estonian (Bilgin *et al.*, 2004; Kahusk and Vider, 2002) and languages such as Hebrew and Arabic, where words are generated from a root that constitutes a kind of 'super-concept' (Black and ElKateb, 2004).

For critical reviews of WordNet, see Kilgarriff (2000) and Lin (1999).

Wrede, Ferdinand (1863–1934)

W H Veith, Universität Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Ferdinand Wrede was born in Berlin as the son of a Music Director. He studied Germanistics and history in Berlin with professors who were very famous at that time. He received his doctor's degree from the university of Berlin in 1886. From 1887 on, he was a collaborator of the *Sprachatlas des Deutschen Reichs [Linguistic atlas of the 'Deutsches Reich']* project, with Georg Wenker as director, in Marburg. In 1890, he qualified as a university lecturer; thereafter (1911–1920), he was honorary Professor, afterwards full Professor of Germanic philology in Marburg. Parallel to his university career, there was his work at the university library of Marburg, ending up with the position of a chief librarian (until 1920). After the death of Georg Wenker (1911), he became the director of the *Linguistic atlas of the Deutsches Reich*, and in 1920, he managed to transfer this project into a permanent institution: the Zentralstelle für den Sprachatlas des Deutschen Reichs und deutsche Mundartforschung [Center for the linguistic atlas of the Deutsches Reich and for German dialect research].

Wrede's fundamental studies first were concerned with Germanic: his dissertation on the Vandals (1886) and his second doctor's degree, 1890–1891 on the Ostrogoths in Italy. However, in the context of these studies, the dialectological aspect was always present, resulting in many activities of this kind. After having become a collaborator of the *Sprachatlas des Deutschen Reichs* project, he started commenting on Wenker's dialect maps (Wrede, 1892–1902). In 1908,

Ferdinand Wrede was born in Berlin as the son of a Music Director. He studied Germanistics and history in Berlin with professors who were very famous at that time. He received his doctor's degree from the university of Berlin in 1886. From 1887 on, he was a collaborator of the *Sprachatlas des Deutschen Reichs [Linguistic atlas of the 'Deutsches Reich']* project, with Georg Wenker as director, in Marburg. In 1890, he qualified as a university lecturer; thereafter (1911–1920), he was honorary Professor, afterwards full Professor of Germanic philology in Marburg. Parallel to his university career, there was his work at the university library of Marburg, ending up with the position of a chief librarian (until 1920). After the death of Georg Wenker (1911), he became the director of the *Linguistic atlas of the Deutsches Reich*, and in 1920, he managed to transfer this project into a permanent institution: the Zentralstelle für den Sprachatlas des Deutschen Reichs und deutsche Mundartforschung [Center for the linguistic atlas of the Deutsches Reich and for German dialect research].

Wrede's fundamental studies first were concerned with Germanic: his dissertation on the Vandals (1886) and his second doctor's degree, 1890–1891 on the Ostrogoths in Italy. However, in the context of these studies, the dialectological aspect was always present, resulting in many activities of this kind. After having become a collaborator of the *Sprachatlas des Deutschen Reichs* project, he started commenting on Wenker's dialect maps (Wrede, 1892–1902). In 1908,

he founded the series *Deutsche Dialektgeographie* in which dialect monographs, mostly on the basis of direct investigations other than Wenker's indirect method, were published. This series can be compared with the famous *Archivio glottologico italiano* [*Archive for Italian language studies*], founded in 1873 by G. I. Ascoli.

Wrede can claim five major linguistic achievements:

1. He initiated many scientific projects, e.g., the Hessen-Nassauisches Wörterbuch, an area dialect dictionary for which his student Luise Berthold was in charge.
2. He was the real creator and intellectual mentor of the Marburg school of dialectology with many disciples.
3. He interpreted the dialect maps (e.g., Wrede, 1892–1902, 1924) and classified the German dialects (cf. Veith *et al*., 1984–1999, map. E5).
4. He expanded dialect research over all areas in Central Europe in which German dialects were spoken (Switzerland, Southern Tirol, Liechtenstein, Austria, parts of Czechoslovakia, etc. Wenker's questionnaire was translated and then used for dialect mapping).
5. He initiated the edition of Wenker's dialect maps as an atlas (*Deutscher Sprachatlas auf Grund des von Georg Wenker begründeten Sprachatlas des Deutschen Reichs* . . . [1926–1956]).

Wright, Joseph (1855–1930)

M Pierce, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Joseph Wright certainly had one of the most unusual early lives of any Oxford professor ever. Born on October 31, 1855 in Thackley, Yorkshire, England, Wright went to work in a mill at the age of six, and did not learn to read and write until he was 15. The turning point for him came in 1870, during the Franco-Prussian War, when he became jealous of his literate colleagues who could read newspaper articles about the war. He therefore taught himself to read and write, and also began attending a night school designed for mill workers. He made such rapid progress that after three years of study he was able to start his own night school, while still working at the mill. In 1876, the mill temporarily closed, and Wright therefore decided to use his savings on a term of study in Heidelberg. He traveled first to Cologne via Antwerp, where he spent several weeks improving his German, and then to Heidelberg, where he studied mathematics for eleven weeks (all the time he could afford). When he returned to England, he taught mathematics at various schools for a number of years. In the spring of 1882 Wright returned to Germany, where he originally planned to study mathematics but quickly switched to studying philology. Wright spent the next several years in Germany, studying in Heidelberg, Freiburg im Breisgau, and Leipzig, where he acquired a profound knowledge of the Indo-European languages, as well as a solid foundation in phonetics and dialectology. He completed his doctorate at Heidelberg in 1885. During his

he founded the series *Deutsche Dialektgeographie* in which dialect monographs, mostly on the basis of direct investigations other than Wenker's indirect method, were published. Wright, Joseph (1855–1930)

M Pierce, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Joseph Wright certainly had one of the most unusual early lives of any Oxford professor ever. Born on October 31, 1855 in Thackley, Yorkshire, England, Wright went to work in a mill at the age of six, and did not learn to read and write until he was 15. The turning point for him came in 1870, during the Franco-Prussian War, when he became jealous of his literate colleagues who could read newspaper articles about the war. He therefore taught himself to read and write, and also began attending a night school designed for mill workers. He made such rapid progress that after three years of study he was able to start his own night school, while still working at the mill. In 1876, the mill temporarily closed, and Wright therefore decided to use his savings on a term of study in Heidelberg. He traveled first to Cologne via Antwerp, where he spent several weeks improving his German, and then to Heidelberg, where he studied mathematics for eleven weeks (all the time he could afford). When he returned to England, he taught mathematics at various schools for a number of years. In the spring of 1882 Wright returned to Germany, where he originally planned to study mathematics but quickly switched to studying philology. Wright spent the next several years in Germany, studying in Heidelberg, Freiburg im Breisgau, and Leipzig, where he acquired a profound knowledge of the Indo-European languages, as well as a solid foundation in phonetics and dialectology. He completed his doctorate at Heidelberg in 1885. During his

time in Germany, he also taught school, did editorial work for various publishing companies, prepared a translation of Brugmann (1886) into English (Brugmann, 1888) and wrote a grammar of Middle High German (Wright, 1888). In 1888 he began teaching at Oxford, first on the staff of the Association for the Higher Education of Women, then also for the Taylorian Institution. In his early years at Oxford he supplemented his income by tutoring (mainly preparing students for the army or civil service), teaching German at a girls' high school, and correcting examination papers. In 1891 he became Deputy Professor of Comparative Philology at Oxford, and he retired from Oxford in 1924.

Wright's contributions to linguistics can be grouped into three main areas: dialectology, historical linguistics, and teaching. His interest in dialectology was certainly well developed by the time he first went to Germany; he later published a grammar of the dialect of Windhill in Yorkshire, the town he grew up in, in 1893 (Wright, 1893). Wright's greatest contribution to dialectology is undoubtedly the *English dialect dictionary* (Wright, 1898–1905), which grew out of the realization, early on in the preparation of the *Oxford English dictionary*, that a grasp of the vocabulary of English dialects would be crucial to attaining the goal of an unabridged dictionary. In 1873 the English Dialect Society was formed in Cambridge, and by 1887 it had been decided that the Society should direct the preparation of a dialect dictionary. In 1889, Wright agreed to take over the editorship of the proposed dictionary at some future date, and, by 1894, had begun serving as editor-in-chief. Despite the monumental logistical difficulties that the project faced, especially financial pressures and the problem of finding a publisher, the dictionary was completed at a comparatively rapid pace; the first part appeared in 1898, and the final part was published in 1905. The *English dialect grammar* (Wright, 1905) was published that same year. The work was well received, both because of its high quality and because of the speed with which it had been completed, in fact, Wright secured a yearly pension from the Civil List for it.

Wright's work in historical linguistics, especially his numerous handbooks, is also critical to the development of the field as a whole. He was one of the first scholars in England to preach Neogrammarian doctrines, and his translation of Brugmann (1886) introduced a number of students and scholars in England and America to the new school of linguistics. He also wrote handbooks for a variety of different languages, including Middle and Old High German, Gothic, and Old and Middle English, many of which became classics in the field. His Gothic grammar (Wright, 1910), for instance, was reprinted as recently as 1997, and remains the standard handbook written in English.

Finally, Wright's impact as a teacher cannot be neglected. His most prominent pupils were perhaps his wife Elizabeth Mary Wright, who eventually collaborated with him on a number of projects (including Wright and Wright, 1923, 1924, among others) and J. R. R. Tolkein. The two-volume biography of him by his wife (Wright, 1932) contains numerous letters written to Wright by former students, which uniformly praise his pedagogical abilities. His teaching, as well as his work more generally, was instrumental in establishing linguistics/philology in England.

Writers' Aids

M Dickinson, The Ohio State University, Columbus, OH, USA

Introduction

When using word processors, writers have many tools at their disposal to compose error-free documents: spelling checkers, grammar checkers, and style checkers. With such computer software, writers are able to save time and energy by not having to search for words in a dictionary, can correct words that they might not have even be able to find in a paper dictionary (e.g., not knowing about the silent *k* in *knave* makes it difficult to find), can prevent misunderstandings caused by misspellings or ambiguous structures, and are able to focus less on the form of a document and more on the content. These are all great benefits, assuming that the checkers work correctly or at least in ways that the writer expects. If we understand how these technologies work and therefore what to expect, then we can know their shortcomings and adjust accordingly.

The focus of this article is to outline the aids used for writers, but there is also a need for spelling checking in optical character recognition (OCR), and the technology used for writers' aids is often also used for the correction of OCR output (see Kukich, 1992, and references therein). However, there are differences in how the spelling checking should be optimized. For example, there are likely to be keyboard effects (discussed later) if the input is typed in, whereas there are likely to be confusions between similar-looking characters for OCR misspellings. Thus, spelling checking for OCR may merit different approaches.

Spelling Checkers

Task Definition

Three Different Tasks In providing an extensive literature overview of spelling and grammar checkers, Kukich (1992) gave a taxonomy of tasks involved in writing aids, each task useful for its own purposes. First, there is nonword error detection. This is the task of finding strings in a text that are very unlikely ever to be words. For example, in English, *hte* is not a word. For some purposes, simply detecting a misspelling is enough for the writer, who can then fix it by hand. However, some purposes require in addition a second subtask, that of isolated-word error correction. As the name implies, the goal of this task is to correct errors, or suggest corrections, without taking the surrounding context into account. For example, a corrector could correct *hte* to *the*, but, because it does not look at context, it could not change *there* when it is used incorrectly in place of *their*. To detect such errors, context-dependent word correction is employed. This is the task of correcting errors for which the surrounding context is needed to make clear that there is an error. For instance, *too* used as a numeral will be corrected to *two* when it is surrounded by a determiner and a plural noun (e.g., *the two computers*). Context-dependent word correction overlaps in practice with grammar checking because both refer to strings of indefinite extent.

Kinds of Spelling Checkers Which kind of writing aid we use depends on our purpose (and personality). The need for correction, as opposed to simply detection, arises in the distinction between interactive spelling checkers and automatic spelling correctors. Interactive spelling checkers check errors as the user types, possibly suggesting corrections. Users can determine for themselves the value of the corrections presented. Automatic spelling correctors, however, run on a whole document at once, detecting the errors and automatically correcting them without user assistance. Unless they are 100% accurate, these correctors are less desirable for the task of assisting in writing a document because when the 'best' correction is wrong, the user has to notice and undo the change. Note that emphasizing interactive spelling checkers means that the important tasks to focus on are error detection (context-dependent and context-independent) and the ranking of possible corrections. A user will be more satisfied if the first suggested correction, or one of the first suggestions, is the actually intended word.

Detecting Spelling Errors

Kinds of Spelling Errors

Nonword Errors In order to best detect and correct spelling errors, systems must know what errors to look for and so must know what kind of misspelled and ungrammatical input to expect. There are several main categories of errors that people make when writing, falling into two main groups: typographical errors and true misspellings.

Keyboard mistypings, or typographical errors (typos), are errors in which the person probably knew how to spell the word correctly but made a physical mistake. There are several different kinds of typos, all of which affect how a spelling checker is built.

The first kind of typo involves mistakes caused by hitting the space bar at the wrong time. Splits are errors caused by hitting the space bar in the middle

of a word; that is, a single word becomes two words, such as *quintuplets* becoming *quin tuplets*. Although tokenization – determining word boundaries – is a tricky issue for many languages other than English (and even sometimes for English), most spelling checkers assume that the string that needs to be checked is contained between two spaces. Thus, split errors are difficult to correct because the checker cannot see that the adjacent strings are part of the same word. Run-ons are errors that are caused by not hitting the space bar between two words; that is, two separate words become one, such as *space bar* becoming *spacebar*. Notice that these kinds of typos can interact, and the results may also be words, as in *a tollway* being typed as *atoll way*.

Space-bar issues aside, there are four general kinds of spelling errors. An insertion is when a letter has been added to a word, and a deletion is when a letter has been omitted from a word. Notice that both of these errors change the length of a word. A substitution is when one letter has been typed in place of another letter, and a transposition occurs when two adjacent letters have been switched. By their nature, these last two kinds of errors do not change the length of the word. Identifying these types of errors allows spelling correction software to calculate which are the most common kinds of mistakes and thus which are the most likely corrections. In other words, a distance can be defined between a misspelled word and a potential correction. Furthermore, information can be used about keyboard proximity to calculate error frequency; for example, the proximity of letters on a standard 'QWERTY' keyboard affects how often one letter is typed in place of another (see, e.g., Kernighan *et al.*, 1990).

With these kinds of errors in mind, single-error misspellings (only one instance of an error in the misspelled word) can be contrasted with multi-error misspellings (multiple instances of errors in the misspelling, making them harder to correct). Damerau (1964) found that 80% of misspellings were single-error misspellings, which means that a spelling correction system could focus on optimizing single-error misspelling corrections and still do rather well. Furthermore, Kukich (1992: 388) reported that "most misspellings tend to be within two characters in length of the correct spelling," which allows spelling checkers to make optimizations based on length (e.g., Tillenius, 1996). That is, a spelling checker does not need to search through all possible words, only those within a certain length.

True misspellings, in which the writer did not know how to spell a word, are caused by a lack of knowledge, and the resulting misspellings are often spelled phonetically. The knowledge problem might simply be not knowing how a word is spelled even though the person knows the word, such as not knowing how to spell *onomatopoeia*. A different knowledge problem is to not know a spelling rule, such as that consonants should be doubled when forming the present progressive *-ing* form (e.g., *jog* becomes *jogging*, not *joging*). Or more specific to orthography, the writer may forget spelling rules such as *i* before *e* (e.g., *beleive*). Frequent problems, such as finding *e* before *i*, can be integrated into a spelling checker. Sometimes people's knowledge-based errors reveal what they do know about a word; Mitton (1996) explored several of these errors. People might remember that something is odd about the spelling of the word, but might get that oddity wrong. For example, they might spell *scissors* as *siscors*, remembering only that it has an extra *c*. Or they might use a false analysis of the word, such as spelling *corridoor* for the correct *corridor* on the basis that it has something to do with a door. Or they might spell the word by analogy with another word; for instance, people might spell *leaven* as *leven* based on an analogy with *seven*. These errors are more complex, but information about them still could be used in a spelling checker.

Analogy is one way people spell unknown words, but it is often combined with sound-to-letter correspondences. People may spell a word like it sounds, and so we often find phonetic errors. Thus, spellers may leave out silent letters (*nave* for *knave*) or falsely hypothesize silent letters (*onomanapoeta*), may replace a letter with a similar sounding one (*s* for *c* in *deside*, for *decide*), or may forget the nuances of a rule (*recieve*: *i* before *e* except after *c*). Also, because the same language varies in pronunciation depending on the particular dialect, there might be systematic errors for an individual, such as someone who types *pin* in place of *pen* because in that dialect the two words are pronounced identically. More generally, people often mistake one homophone for another. A common example is to type *there* when *they're* or *their* is meant. These kinds of errors can result in real words, which is more problematic for spelling checkers. Also, because sound-to-letter correspondences vary by language and writing system, the degree to which phonetic errors are a problem varies between languages. For example, Tillenius (1996) reported more phonetic errors for Swedish than for English.

Other general tendencies also allow for more efficient spelling correction. For example, the first character in a word is rarely the source of the misspelling (Kukich, 1992). That is, the misspelled word and the correct spelling usually have the same first letter. This can substantially reduce the search space.

Real-Word Errors The errors discussed so far apply mostly to nonword errors, but we also would like to classify errors that result in real words. To give a characterization of these errors, we briefly look at three kinds of real-word errors: local syntactic errors, long-distance syntactic errors, and semantic errors.

Syntactic errors are simply errors in how words are put together in a sentence; for example, different parts of speech are in the wrong places in a sentence or something is not 'grammatical.' Local syntactic errors are errors in which the syntactic violation is detectable by looking within one or two words in either direction in the sentence. In sentence (1), for example, a verb (*be*) is in the place where a preposition (*by*) should be, and this can be determined by the verb *conducted,* which is only two words before it. Thus, most parsers or statistical error methods would be able to detect this error.

(1) The study was conducted mainly **be** John Black.

Long-distance syntactic errors are more difficult because these involve syntactic violations that are spread out over many more words. In sentence (2), for instance, there is a problem with subject–verb agreement, but it is spread out over eight words. This poses a problem for techniques that rely on local contexts only.

(2) The kids who are most upset by the little totem **is** going home early.

Semantic errors are errors in meaning, that is, in which the sentence structure might sound fine but the sentence does not mean anything or does not mean what was intended. In (3), *minuets* is a plural noun – just like *minutes* – but it does not make sense in this context. These errors are difficult for any system because they seem to require semantic processing; however, even some kind of co-occurrence analysis might prove useful to catch some of these errors (*see* **Collocations**).

(3) They are leaving in about fifteen **minuets** to go to her house.

Nonword Error Detection

Dictionary Methods Detecting spelling errors that result in nonwords can be done by using a dictionary or spelling list: if the word is not in the dictionary, it is a misspelling. However, there are several issues to consider in constructing a dictionary and looking words up in the dictionary (*see* **Computational Lexicons and Dictionaries**).

First, we must realize that any dictionary is inherently incomplete due to the productivity of language. That is, new words are continually entering the lexicon, such as *d'oh*, while at the same time old words are leaving. For example, in Shakespeare's time, *spleet* 'split' (*Hamlet* III.2.10) was a word and thus correctly spelled, whereas today it is not. In addition, foreign words, hyphenations, derived words, and proper nouns bring new words into a language and prevent a dictionary from being exhaustive. Notice that trying to include every word, such as all proper nouns, for example, is not always a good idea. Including the proper last name *Carr* may result in not finding a misspelling in *The Great American Carr Show.* For the same reason, when constructing a dictionary, we have to consider which rare words we want in the dictionary – they might become confounded with actual misspellings. For example, *teg* 'a sheep in its second year' is a word, but for the majority of English speakers it is unknown and is probably a misspelled form of *tag* or *beg* or some such word. Likewise, we might want to maintain separate dictionaries for particular domains: For the average user, *memoize* is a misspelling of *memorize*, but for computer scientists it is a technical term. This highlights the fact that a dictionary must be constructed with the users in mind. As another example of user-tailoring, a dictionary should also be dialectically consistent. The British spelling *colour* and the American spelling *color* are both correct spellings within their dialects, but misspellings otherwise. (See McIlroy, 1982, for discussion of construction of a spelling list.)

A more general issue for dictionary construction is whether or not to include inflected words as separate entries in the dictionary (*see* **Inflection and Derivation**). That is, should *car* and *cars* be stored separately? Or should *car* be stored as a single entry, indicating its part of speech (noun) and whether or not it is regular (i.e., takes the standard *-s* plural ending). The choice is one of efficiency and where to allocate the work. If the inflected words are separate entries, then the lookup mechanism is straightforward but there is an increase in the number of words. If inflected words are not stored as separate entries, on the other hand, then there are far fewer lexical entries but we have to strip the affixes (prefixes and suffixes) from the words before looking them up. Furthermore, we have to handle exceptions to the affix rules in some systematic way, possibly by having separate entries, for example, for *man* and *men*. And there must be a special note on *man* that it is irregular, so that *mans* will not be considered a correct spelling; that is, we have to prevent the overgeneralizations of the affix rules.

When dealing with thousands of words, looking up those words becomes nontrivial; each word has to be stored somewhere in computer memory and finding the word takes time. Thus, an efficient storage and

lookup technique is also needed. That is, the words could be stored alphabetically and each word encountered could be searched for, but the words in English are not evenly distributed over the entire alphabet – the number of words that start with *x* are much fewer than those that start with *s*. Thus, more-efficient lookup techniques are used. Computer scientists and software engineers study and develop various ways to evenly distribute word entries into memory, thus quickening word lookup.

N-Gram Methods Dictionaries are not the only way to check whether a word is misspelled or not; researchers have also tried a technique known as *n*-gram analysis (see the references in Kukich, 1992). An *n*-gram in this context refers to a string of *n* characters in a row; for instance, *thi* is a 3-gram (or trigram). Note that *thi* is a possible trigram of English (*this*), whereas *pkt* is not. Thus, we can store all the possible *n*-grams, for a certain *n*, for a given language and determine whether each new string encountered has only valid *n*-grams. These valid *n*-grams can be derived from a corpus, assuming it has few or no misspellings (*see* **Corpora**).

A common technique is to use 2-grams (bigrams) and to store them in an array. This can be done with positional information included or not. A nonpositional bigram array is an array of all possible and impossible bigrams in a language, regardless of the bigram's position in a word. A positional bigram array, on the other hand, is an array of possible and impossible bigrams in a language for a particular position in a word, for example, word ending. Thus, *mm* is a possible bigram in English (e.g., *humming*), but it is not a valid word beginning and so would not be in the positional bigram array for word beginnings. *N*-gram techniques store data very compactly, thus having a huge advantage over dictionaries in that respect. However, they detect only misspellings that contain very odd sequences of characters; misspellings caused by writers are more likely to contain valid character sequences. Combining *n*-gram analysis with a dictionary, however, can lead to effective and efficient spelling checking.

Isolated-Word Spelling Correction

Isolated-word spelling correction attempts to correct a misspelled word in isolation, that is, irrespective of the surrounding words. This task deals with nonword errors, the kinds of errors discussed in the previous section. Notice that we cannot expect 100% correctness from isolated-word spelling correctors. When humans were given the same task – correcting nonwords without being given the context – their accuracy was between 65% and 83%, the average being 74% (Kukich, 1992).

There are three main steps for a spelling checker in correcting errors:

1. error detection (already described)
2. generation of potential, or candidate, corrections
3. ranking of candidate corrections

In some techniques these steps are conflated into a single process. Notice that ranking the candidate corrections is useful in interactive spelling correctors, for which a human makes the ultimate decision, because – similar to search engine rankings – the higher up in the list the correct spelling is, the more quickly the user can approve the correction.

Generation of Candidate Corrections There are many ways to generate potential corrections, two of which are presented here. Whatever the technique, the task is to take an identified misspelling and find a set of possibly correct spellings.

Rule-based techniques generate candidate corrections by means of written rules or transformations from a misspelling to a correct spelling. For example, a rule could look for the misspelling *hte* and generate *the* as a potential correction. Rules may further specify whether the correction is the only possible correction and thus act as a kind of ranking. Rule-based techniques can obviously be very effective, especially for high-frequency errors such as *hte*; however, they are often very narrow and specific, such as the *hte* rule, which covers only one single misspelling of *the*; a separate rule has to be written to correct *teh*. Furthermore, rules have to be written, and they may not capture all the spelling errors humans might make. With recent advances in computational linguistics, however, there is the possibility of the automatic derivation of rules (Mangu and Brill, 1997).

Similarity-key techniques store words (correct spellings) with similar properties in the same 'bucket.' That is, words with similar spellings or similar sounds and of about the same length are put together into one slot. The similarity key for a misspelling is then automatically calculated and points to a bucket. For example, in the SOUNDEX system developed by Odell and Russell (1918), the word *nub* would be assigned the code N2: an N for the first letter, a 0 (which is later eliminated) for the vowel, and a 2 for a labial (*b*, *p*, *f*, *v*). The words *nob*, *nap*, and so on will also be in this bucket. When a misspelling is found, its similarity key is calculated and a list of candidates from the same bucket is obtained. So, the list of candidates for the misspelling *nup* will be *nub*, *nob*, *nap*, and all the other words in bucket N2.

Ranking of Candidate Corrections Once the list of candidate corrections has been generated, we would like to filter out the unlikely candidates and/or rank the candidates to see which candidate is the best. Again, two techniques are presented here, although there are many more methods in existence.

Probabilistic techniques are based on the intuition that some corrections are better than others. In a broad manner, we might use the probability of one word being typed in place of another to rank candidates, but deriving these probabilities is not feasible. Instead, the transition probabilities and the confusion probabilities of letters are used. Transition probabilities are the probabilities of one character following another; for instance, the probability of *q* being followed by *u* in English is essentially 100%. Confusion probabilities are the probabilities of one character being substituted for another; for example, the chance of an *m* being typed for an *n* is higher than a *q* being typed for an *n* on an English QWERTY keyboard. Taking the misspelling as input, transition and confusion probabilities can be used to find which dictionary entry maximizes those probabilities (i.e., matches the misspelling best). This phase of spelling correction can be implemented with Markov models, neural networks, or various other methods that deal with probabilities (*see* **Language Processing: Statistical Methods**).

Another way to rank candidate corrections is to assign each a 'distance' value telling how far off it is from the misspelling. A specific instance of this is called edit distance, which measures how many operations – insertion, deletion, substitution, and transposition – it would take to convert a misspelling into the correct spelling. The candidate with the minimum edit distance is the top-ranked one. For example, for the misspelling *obe* the word *oboe* has a distance score of 1 (insertion of *o*), whereas *hobo* has a score of 2 (insertion of *h* and substitution of *o* for *e*), so *oboe* is the better choice. Of course, a word such as *robe* also has a distance score of 1, so to give a ranking with no tie scores we need to add more information. Instead of giving a value of 1 for each operation, we can use probabilities to determine which operations are more likely. To return to our previous example, a greater edit distance would be given to substituting *q* for *n* than would be given to substituting *m* for *n*.

Whether probabilities are used or not, the minimum edit distance for a word can efficiently be found by using dynamic programming techniques. That is, there are many possibilities for changing a misspelling into a word – we could perversely derive *oboe* from *obe* by deleting *o*, changing *b* to *o*, inserting *b*, and finally inserting *o*. Although this might seem ludicrous, the computer has no way of knowing *a priori* which operations will result in the best fit. Dynamic programming techniques reduce the search space.

Grammar Checking and Context-Dependent Word Correction

The problem of context-dependent word correction is that of detecting and correcting errors that result in true words. For example, the use of *There* in *There house is nice* is wrong, but it is still a real word. This kind of spelling correction is akin to grammar checking because we have to know the use of a word within a given sentence in order to know that it is wrong – that is, that *There* is not a possessive modifier. So, the same techniques that attempt to find misspellings can also be used to find grammar mistakes. The line between context-dependent word correction and grammar correction is a fine line, and so they are treated together here. The usefulness of correcting real-word errors is readily apparent, but becomes more striking when we realize that 30–40% of spelling errors result in real words (Wing and Baddeley, 1980; Kukich, 1992).

Rule-Based Techniques

A very simple technique for detecting and correcting grammatical errors is simply to write rules that spot a pattern and alter it. For example, a rule could match the pattern of *some* or *certain* followed by *extend*, and change *extend* into *extent* (Naber, 2003). Much commercial software uses such rules. Again, the disadvantage is that the rules have to be handwritten, and they will be necessarily incomplete because people make new errors (and new kinds of errors) all the time.

Bigram Grammar Correctors

There are many different statistical techniques we can use to detect and correct grammatical errors in a text; one such technique uses bigram correctors. Instead of referring to pairs of letters, here 'bigram' (or 2-gram) refers to a sequence of two words in a row. Statistical bigram grammar correctors use the probability of one word following another to determine whether an error has been made. For example, *conducted be* is not a likely word bigram in English, but *conducted by* is. A major problem with such techniques is that it is hard to estimate the probabilities of all possible bigrams from a corpus, given that language is infinite. That is, both *conducted be* and *conducted by* might never appear in a corpus, but we still know that only one of them is correct. Thus, some methods employ bigrams of parts of speech to make the probabilities

easier to gather. For example, they compare the probability of a verb followed by a preposition with the probability of a verb followed by another verb. This approach requires a part-of-speech tagger (*see* **Part-of-Speech Tagging**), but the generality gained increases the chances of finding errors with low-frequency words. Given that some words are high frequency and that certain words, such as verbs, have selectional properties, we can also use a mixture of words and parts of speech for the bigrams.

Machine-Learning Techniques

Another technique, presented by Golding and Roth (1999), among others, is the use of machine learning, more specifically viewing the context-dependent spelling correction task as a word disambiguation task. This is done by building 'confusion sets,' which consist of words that are potentially confounded with one another. So, a set might contain the words *there*, *they're*, and *their*, and the task of the system is to figure out, whenever any of the words in the set is seen, which of them is meant in a given context. (Note that this deals only with real-word errors and will require a separate module to map nonwords to a confusion set in order to handle nonword spelling errors.)

To do this, different features of context are used; common kinds of features are context words and collocations. Context words capture a broad 'semantic' context because they are simply words within a certain distance of the word in question. For example, it is useful for the spelling corrector to know whether *cloudy* appears within the surrounding ten words if the confusion set we are dealing with is composed of *whether* and *weather*. Collocations, on the other hand, capture a very local context – essentially *n*-gram information. With the same set of *whether* and *weather*, for instance, a collocation might be the word in question followed by *to* and a following verb (e.g., *whether to run*) (*see* **Collocations**).

This information must be integrated into a particular machine-learning algorithm, such as decision lists, Bayesian hybrids, transformation-based learning, Winnow-based approaches, or latent semantic analysis (see, e.g., Golding and Roth, 1999, and the references therein; *see* **Language Processing: Statistical Methods**).

Grammar-Based Techniques

Akin to research in intelligent computer-assisted language learning (ICALL), grammar-based research in grammar checking uses parsing failures to indicate potential real-word errors. The system uses a grammar (often a mixture of syntactic and semantic information) and a mechanism for parsing; when the parser using that grammar fails, it assumes an ill-formed input. There are some general approaches to dealing with ill-formed input, two of which are given here: relaxation-based and expectation-based techniques (Kukich 1992).

Relaxation-based techniques relax the parsing process to allow errors, with the idea that no errors should be ignored. This might involve relaxing the parsing procedure so that parsing failures are simply allowed, noting where in the parsing the failure took place. Alternatively, we might write grammar rules that predict types of failures; for example, a rule might be expressly written that allows a first-person singular subject to combine with a third-person singular verb, indicating the construction to be erroneous.

Expectation-based techniques build up a representation as the input comes in and predict a list of words that the system expects to see next. If the next word in the input is one of those words, everything is fine; if the next word in the input is not in the list of expected words, it is taken to be an error and the list of expected words becomes the list of potential corrections.

Although grammar-based techniques can be highly effective and are intuitively appealing, they are not without problems. First, as with dictionaries, grammars are likely to be incomplete. Not only are there new words to deal with, but people also continue to create novel expressions and turns of phrases. Second, it is not always easy for the various techniques to detect the exact source of a parsing failure. For example, in *The study was conducted be John Black*, there are two verbal phrases (*The study was conducted* and *be John Black*), but which word needs to be altered in order to fix this is not obvious to a parser.

Style Checkers

Style checkers can check for violations of a particular style, such as that prescribed by MLA standards. The constructions may still be correct English, for instance, but are just unacceptable for the purposes of the current document. For example, we might want to have a style checker find and change singular uses of *data*, such as *the data is* if the style dictates that this word is plural. Or certain words may be disallowed or marked; for instance, the use of *you* is unacceptable for most formal documents. Often, style checkers are used to detect deprecated constructions; for instance, they might flag the use of too many passive constructions, which are usually dispreferred in 'clear' writing, or they might disallow split infinitives (e.g., *to boldly go*). As with grammar checkers, style checkers might examine only a small window of context; often, a passive construction with many words between the be verb and the passive participle will go

undetected as a passive (e.g., *was very readily and quickly available*).

Notice that, despite a functional distinction between grammar and style checkers, from an implementation point of view they are essentially the same. The main difference is flexibility. A style checker should be easy to turn on and off, so that users can decide whether to have a particular style in place, depending on the purpose of the document.

Conclusion

The ultimate spelling checker still remains to be built, but current technology is quite good at detecting and correcting various spelling and grammar errors. The different techniques presented here represent an overview of current Natural Language Processing technologies. Thus, as linguistic technologies improve, in general (part-of-speech tagging, machine learning, etc.), writers' aids should also improve. However, until writers' aids are 100% effective at detecting and correcting errors, they should be used with some caution. A study at the University of Pittsburgh showed that students had more errors when they used a spelling checker than when they handcorrected their papers (Galletta *et al.*, 2005). Thus, despite the usefulness of writers' aids, writers must still carefully supervise the editing of their documents.

This article provides a brief overview of research exploring the cognitive processes associated with text production by human writers, focusing on the handwritten or keyboarded production of coherent, multi-sentence texts. Currently, written production, in this sense, is less well understood than either text comprehension or spoken production.

Text production is a skill that typically starts to develop in children at around the age of six or seven and as a result of extensive specific instruction. This contrasts with the ability to participate in

undetected as a passive (e.g., *was very readily and quickly available*).

Notice that, despite a functional distinction between grammar and style checkers, from an implementation point of view they are essentially the same. The main difference is flexibility. A style checker should be easy to turn on and off, so that users can decide whether to have a particular style in place, depending on the purpose of the document.

Conclusion

The ultimate spelling checker still remains to be built, but current technology is quite good at detecting and correcting various spelling and grammar errors. The different techniques presented here represent an overview of current Natural Language Processing technologies. Thus, as linguistic technologies improve, in general (part-of-speech tagging, machine learning, etc.), writers' aids should also improve. However, until writers' aids are 100% effective at detecting and correcting errors, they should be used with some caution. A study at the University of Pittsburgh showed that students had more errors when they used a spelling checker than when they handcorrected their papers (Galletta *et al.*, 2005). Thus, despite the usefulness of writers' aids, writers must still carefully supervise the editing of their documents.

Writing and Cognition

This article provides a brief overview of research exploring the cognitive processes associated with text production by human writers, focusing on the handwritten or keyboarded production of coherent, multi-sentence texts. Currently, written production, in this sense, is less well understood than either text comprehension or spoken production.

Text production is a skill that typically starts to develop in children at around the age of six or seven and as a result of extensive specific instruction. This contrasts with the ability to participate in

spoken dialogue, which develops much earlier and largely through exposure to parents' speech. A good stepping-off point for describing the cognitive psychology of text production is to ask what mental processing is required to produce text over and above that which is required for participation in dialogue. First, in most contexts and particularly those typically studied by researchers, writers become aware of the need to write something before they have a definite message to communicate. Planning what to say is, therefore, a major feature of most writing tasks. Second, writers need to be able to maintain and develop meaning across a number of sentences. Turn taking in dialogue both allows immediate feedback on the comprehensibility of an utterance and provides a stream of cues that aid decisions about what to say next. In the absence of an interlocutor writers must find alternative strategies for maintaining coherence. Third, unlike speech, writing requires the planning and execution of letter shapes (or keystrokes) and the retrieval of word spellings. Fourth, one benefit that writing has over speech is that it is possible to review and edit output before it reaches its audience. Text production is therefore necessarily complex, requiring coordination of high-level processes for determining content and structure, and low-level processes associated with producing words on the page.

A chapter by Hayes and Flower (1980) is frequently cited as providing the first general cognitive theory of text production. Their model characterized writing as a problem-solving activity: Writers identify one or more goals for their text, described in terms of the effect that the text will have upon intended readers, and then work backwards from this to identify plans of action by which these goals might be achieved. Hayes and Flower described three processes: planning (determination of content and structure), translating (the process by which this structure is realized as full text), and revising (checking that the text does, in fact, fulfill communicative goals). Studies in which writers are asked to think aloud while producing text suggest that each of these three processes is available to the writer at any point during production. Although planning is more likely to occur near the start of a writing task, and revision towards the end, producing a document typically entails multiple plan-translate-review cycles. Hayes and Flower provided hypotheses about how planning, translating, and revision processes might function, although the problem-solving framework in which these were couched has typically not been adopted in subsequent research. Many researchers have, however, used Hayes and Flower's terminology.

Planning Content

How writers determine content (a process called 'generating' in the Hayes and Flower model) varies with task, and with writer maturity and motivation. In all cases, however, generating will entail cued retrieval from long-term memory (LTM). Writers temporarily hold relevant concepts active in working memory. These concepts act as memory probes and activation spreads from them to related concepts in LTM. Concepts retrieved in this way are then either written down in note form for later use or translated directly into text. Studies exploring the time course of the planning process suggest that propositions tend to be retrieved in repeated bursts of activity interspersed with lulls during which there is no retrieval. Activity during these lulls is thought to be associated, at least in part, with refreshing the probe.

Differences among writers, and particularly developmental differences, are likely to be associated with the ways in which probes are constructed. Novice writers and writers with low motivation may refresh probe content more or less randomly, or simply rely on immediately available cues – exact words or phrases contained within the text of the writing assignment, for example. Content generated in this way will tend to follow a path of least resistance through a writer's existing knowledge about a topic. Bereiter and Scardamalia (1987) described this stream-of-consciousness approach to generating content as 'knowledge telling.' They contrast this with 'knowledge transforming,' an approach that is available only to more experienced writers. Knowledge transforming involves, in Bereiter and Scardamalia's terms, a dialectic between discourse space and content space: instead of probing memory with whatever cues are most readily available, probe selection is constrained by rhetorical considerations. Content is thus determined not just by a writer's knowledge of the topic but also by the effect that they wish to have on their intended readers. One result of knowledge transforming is that the first idea that occurs to a writer is unlikely to become the main focus of their text. Another is that writers may, as a direct result of writing about a topic, discover new ideas or arguments.

Planning Rhetorical Structure

Writers need not only to retrieve relevant propositions but also to tie these together into a coherent whole. Hayes and Flower identified a specific subprocess dedicated to organizing content prior to its realization as full text. This does not appear to be essential, however. Some writers, and particularly novices, add ideas into the text in more or less the

order in which they are retrieved. Where writers do engage in deliberate rhetorical structuring prior to producing full text, they often then deviate from this structure during translation.

Beyond these general observations, however, the processes by which coherent structure is achieved are poorly understood. Some recent research has taken as a starting point the assumption that coherent text comprises a hierarchy of text spans linked by rhetorical relations. Using an analytic procedure called PISA (procedure for incremental structural analysis), an approach similar to rhetorical structure theory, Schilperoord and coworkers have demonstrated an association between text structure and writers' patterns of pausing: writers tend to pause for longer at rhetorically defined text span boundaries, and this effect is independent of the pausing associated with orthographic features such as sentence and paragraph boundaries. Developmentally, more experienced writers tend to produce texts with deeper and more branched structures. This may be because as writers mature, their discourse knowledge – the range of possible rhetorical relations that they have at their command – expands. Alternatively, this effect may be due to developmental increases in short-term storage capability. Producing a highly branched rhetorical structure is likely to involve keeping a greater number of propositions active in short-term memory than is necessary when producing less complex structures.

Translating Plans into Text

A central concern of recent research has been the extent to which processing low-level tasks – developing syntax, and spelling and transcribing words – interferes with retrieving and organizing content. In a series of experiments exploring verbal memory in children, Bourdin and Fayol have demonstrated that written recall is substantially poorer than spoken recall. This effect is largely absent in adults, suggesting that as spelling and handwriting are practiced they make fewer demands on higher-level cognitive mechanisms. However, even in adults there are some contexts in which transcription and content retrieval compete for cognitive resources. Mature writers may reduce the probability of conflict by adopting two writing-specific memory management techniques. Several researchers have suggested that experienced writers construct retrieval structures that allow very rapid access to content stored in long-term memory. This strategy, termed 'long-term working memory,' liberates cognitive resources during translation by reducing the information that must be held in short-term memory. Another widely used strategy for reducing the possibility of cognitive overload involves dividing up the writing process into discrete subtasks by, for example, outlining content and structure in note form before producing full text. In experimental contexts this outlining tends to result in the production of higher-quality text. Arguably, this is because separating out planning and translation processes removes the possibility that they will compete for the same resources.

Reviewing and Revision

Most writers in most contexts spend time reading back over the text that they have written. For example, in one study 15-year-olds producing short argumentative essays spent, on average, 20% of their total writing time in some sort of reviewing activity. Reviewing, however, takes a variety of forms. Writers regularly pause and read back over the two or three sentences they have just written. This local reviewing appears to serve more to cue in new sentences than to edit or repair existing text. Curiously, preventing competent writers from reading what they write (by, for example, turning the computer screen off while competent typists word process) does not typically affect the quality of the final text. There appears to be a trade-off between the benefits of knowing (and possibly editing) what has just been written, and the detrimental effect of the additional load that local reviewing imposes on short-term memory.

The extent to which full read-evaluate-edit cycles occur varies considerably across writers and tasks, with typically very few occurrences in novices' writing. Little is known about the cognitive processes that underlie evaluation, although there is a general assumption that editing is prompted by the writers perceiving dissonance between their intended message and the message that they infer from their text. This dissonance may occur because the writer lacks the necessary lexical or rhetorical knowledge to convert their preverbal message into text, although there is some evidence that suggests that writers are only able to detect those problems that they have the necessary knowledge to repair. Another cause of dissonance may arise because writing results not only in an external expression of a writer's existing ideas about a topic but often also in an internal realignment or development of those ideas within the writer's mind. Thus, when a writer experiences dissonance when reading back over earlier paragraphs, this may not be because at the time of writing the writer's translation of ideas into text was inaccurate. It may instead be because the writer's thinking has since moved on. Strategically, it is possible to capitalize on this dynamic interaction between text and thought by

deliberately producing multiple rough drafts, allowing meaning to develop with the text. This technique is sometimes called 'free' or 'generative' writing.

Writing Materials

A Gaur, Surbiton, Surrey, UK

© 2006 Elsevier Ltd. All rights reserved.

Over the last six millennia, many different materials have been used for writing: stone, wood, metal, animal skins, leaves, bones, shells, clay, wax, pottery, silk, cotton, papyrus, ivory, bamboo, bark, palm leaves, linen, and paper. Many of them often decisively influenced not only the way a particular script developed, but also the shape of the manuscript (book).

The main reason for choosing a particular material is without doubt its geographical availability. Bamboo seemed the obvious answer for ancient China, palm leaves for South and Southeast Asia, clay bricks for Mesopotamia, and papyrus for Egypt, while the plant grew plentifully in the Nile valley. Another decisive factor is the technical ability to transform raw material. Whereas stone, wood, bones, bamboo, tortoiseshells, the bark of trees, and ordinary leaves can be used, either in their original form, or after only a minimal preparation, material such as metals (gold, silver, copper, lead), ivory, and the materials originally designed for another purpose (cotton, linen, silk, and ostraca) presuppose a certain amount of technical know-how. Into this category also fall the materials specially devised for writing: papyrus, clay bricks, parchment, and paper. And finally there are the effects of cultural determinism. Leather, for example, was never used further east than Iran. Buddhists and Hindus alike would have viewed with horror the idea of writing their sacred text on the skins of slaughtered animals.

Another broad division is that between imperishable materials (such a stone, metal, bones, and shells) and perishable materials, including palm leaves, bark, textiles, papyrus, and paper. To engrave on stone, and to write on papyrus, requires different instruments and different techniques; it also produces visibly different results. Monumental Egyptian hieroglyphics cut in stone look entirely different from the demotic script written on papyrus, yet the difference is only one of style, not of substance. Whereas in monumental inscriptions, individual characters are usually well defined and separated from each other, perishable materials encourage more rounded letters and a tendency toward connecting lines between the letters: in

deliberately producing multiple rough drafts, allowing meaning to develop with the text. This technique is sometimes called 'free' or 'generative' writing.

Over the last six millennia, many different materials have been used for writing: stone, wood, metal, animal skins, leaves, bones, shells, clay, wax, pottery, silk, cotton, papyrus, ivory, bamboo, bark, palm leaves, linen, and paper. Many of them often decisively influenced not only the way a particular script developed, but also the shape of the manuscript (book).

The main reason for choosing a particular material is without doubt its geographical availability. Bamboo seemed the obvious answer for ancient China, palm leaves for South and Southeast Asia, clay bricks for Mesopotamia, and papyrus for Egypt, while the plant grew plentifully in the Nile valley. Another decisive factor is the technical ability to transform raw material. Whereas stone, wood, bones, bamboo, tortoiseshells, the bark of trees, and ordinary leaves can be used, either in their original form, or after only a minimal preparation, material such as metals (gold, silver, copper, lead), ivory, and the materials originally designed for another purpose (cotton, linen, silk, and ostraca) presuppose a certain amount of technical know-how. Into this category also fall the materials specially devised for writing: papyrus, clay bricks, parchment, and paper. And finally there are the effects of cultural determinism. Leather, for example, was never used further east than Iran. Buddhists and Hindus alike would have viewed with horror the idea of writing their sacred text on the skins of slaughtered animals.

Another broad division is that between imperishable materials (such a stone, metal, bones, and shells) and perishable materials, including palm leaves, bark, textiles, papyrus, and paper. To engrave on stone, and to write on papyrus, requires different instruments and different techniques; it also produces visibly different results. Monumental Egyptian hieroglyphics cut in stone look entirely different from the demotic script written on papyrus, yet the difference is only one of style, not of substance. Whereas in monumental inscriptions, individual characters are usually well defined and separated from each other, perishable materials encourage more rounded letters and a tendency toward connecting lines between the letters: in

other words a cursive form of writing. The purpose of the written information also influences the material chosen: public pronouncements, visible for all who can read, are mostly written on imperishable material; personal correspondence, matters relating to day-to-day administration and commerce, tend to use a cursive form of writing on perishable material such as papyrus or paper. It is doubtful whether without the generous supply of papyrus in Egypt, demotic writing would have developed and prospered. Similarly, the easy availability of paper, brought to Europe by the Muslims in the 12th century, played a decisive role in the quick spread of printing after the 15th century: one Bible printed on parchment, it was soon discovered, demanded no fewer than three hundred sheep skins.

Some materials were specially devised for writing, such as papyrus and paper. Both require an already quite complex manufacturing process. Papyrus dominated the cultural life, first of Egypt, then of the Mediterranean world, for almost three millennia. It is generally considered to be an invention made by Egyptian priests, and the earliest (un-inscribed) examples go back to 3300 B.C. Papyrus was not only a highly successful writing material, it also became a profitable state monopoly. Firmus, the imperial Roman pretender, boasted in 273 A.D. that he could keep a whole army on the revenues from the papyrus trade. Much has been written about the way papyrus was manufactured. Basically, carefully cut pieces from the inner stem of the plant were laid cross-wise on a special table, pressed and beaten together, and then dried in the sun. Some type of adhesive (suggestions range from Nile water and gum, starch, and a special type of glue, or hot water and vinegar) was without doubt needed, but none of the Arab writers is very clear on this point. Several sheets stuck together form a scroll with writing being done on one side. With the beginning of the Christian era, papyrus became increasingly scarce and in consequence more expensive. There is some irony in the fact that the word 'paper,' the name of the material that eventually supplanted papyrus in the 11th century, comes, via French and Latin, from the Greek word 'papyros.'

According to the Chinese historian Fan Yie (397–445 A.D.), Cai Lun, a eunuch at the court of the Han Emperor Wu Di, invented paper in 105 A.D., but Cai Lun was probably more of a supervisor, and paper the evolutionary outcome of a process connected with already existing knowledge of how to make silk paper. As a writing material, silk had performed well with brush and ink, and some 4th and 5th century B.C. Chinese writers mention it in a manner that implied frequent use. But even silk paper (made out of old silk rugs) soon proved too expensive to satisfy the increasing demands of an ever-growing administration. Paper was cheaper and it offered the possibility of recycling waste products (fish nets, old linen rags, mulberry bark, laurel, waste hemp, etc.). The process of making paper is, however, difficult, going through various time-consuming stages. Soon paper became a closely guarded state monopoly that never spread further west than Chinese Turkestan. It was only in 751 A.D. when the Muslim Governor of Samarqand took captive a large number of prisoners, some of them adept in the art of papermaking, that the knowledge spread outside China. From there it reached Baghdad, Damascus, Hamah, Tripoli, Cairo, North Africa, and eventually in the 12th century the Muslim-influenced part of southern Europe.

Some writing materials had a decisive influence not only on the shape and formation of letters, but also on the direction of the script and the shape of the manuscript (book); they were mostly bamboo, leather/parchment, clay tablets, and palm leaves.

Bamboo, cut into small strips, was widely used in ancient China. The Chinese character for 'archive' and 'register' (*ce*), authenticated from at least the 14th century B.C., seems to portray narrow slips of bamboo laced together. In the same way, the number of books registered in the Annals of the Western Han dynasty (206 B.C. to 25 A.D.) were counted in 'bundles of bamboo.' The shape of those early bamboo slips has probably influenced the vertical direction of the Chinese script. Later, when the Chinese administration moved to areas where bamboo was less easily available, wooden slips were used, shaped in the same way.

The earliest surviving example of leather comes from Egypt (*ca.* 2500 B.C.). Used without curing (smoking) and processing (manipulation with oil), animal skin decays quickly; but once so treated it is durable and flexible. By a process of tanning, which renders it nonputrescent and impervious to water through a tanning agent (probably acacia pod in Egypt, oak bark in Europe), skin can be transformed into leather. Leather used the scroll format since only one side is suitable for writing. Today leather scrolls still play an important part in Jewish ritual: according to the Talmud, the Book of Law must at all times be written on skin, and even today all synagogues have their leather or parchment Torah scrolls.

A decisive step forward was made about 150 B.C. when, according to Pliny the Elder, King Eumenes II 'invented' parchment. Though parchment does indeed take its name from the city of Pergamum, it is more likely the result of a gradual development. Parchment already needs a fairly complex manufacturing process: the skin has to be treated with lime, dehaired, defleshed, stretched, and then treated with pumice. Writing was now possible on both sides. Fragments of

parchment survive from the 2nd century B.C., but it was not before the 2nd century A.D. that it began to rival papyrus in the Roman world, and a further two centuries passed before it was used for the best books. At about the same time, the codex (based on the shape of Roman and Greek wax tablets) began to replace the old scroll format.

Clay tablets were used in Mesopotamia from the middle of the 4th millennium B.C.; they were the first artificially produced writing material. Their shape and quality influenced the form of writing for over three millennia, though the original pictorial signs were probably not replaced by cuneiform signs (as has repeatedly been claimed) because of the difficulties of inscribing round lines on wet clay. But the wedge-shaped impressions made at different angles with a specially designed stylus were the dominant form of writing until the beginning of the Christian era.

Palm leaves, on the other hand, were, until the beginning of the 20th century, the most commonly used writing material in South and Southeast Asia. To make a palm leaf fit for writing, each leaf is split from the central rib, cut to size, boiled, dried, and than rubbed smooth with a stone or a cowry shell. A pile of palm leaves (a book) is secured between two wooden boards, fastened together by a cord running through holes in each leaf. The Chinese pilgrim Xuan Zang, who visited India in the 7th century B.C., describes a large palm-leaf forest in Konkanapura surrounding a Buddhist stupa. Buddhist monasteries were centers of book production and nearby plantations would have ensured an adequate supply of writing materials, just as in ancient Egypt papyrus plantations were maintained around Alexandria and other places where papyrus was manufactured. Three species of palm tree provide material suitable for writing: the talipat palm (*Corypha umbraculifera*), the palmyra palm (*Borassus flabellifer)* and, especially in Southeast Asia, the lontar palm (*Corypha utan*). All Indian, and directly or indirectly all Southeast Asian scripts ultimately developed from Brahmi, a North Indian script first documented at the time of the Emperor Ashoka around the 3rd century B.C. North Indian scripts are often characterized by a long horizontal stroke from which the letters of a word or sentence seem to be suspended: a legacy (according to some scholars) of the stonecutter's tools in monumental inscriptions. This presents no problem if writing is done with pen and ink, but in the south of the subcontinent as well as in Southeast Asia, individual letters were mostly incised with a metal stylus. Since a series of horizontal strokes running parallel to the palm-leaf fibers would have split the leaves, letters began to take on a more rounded shape. But the characteristic oblong shape of the palm leaf imposed itself, for no practical reasons, on many paper, ivory, and metal manuscripts of Southeast Asia.

There are, finally, the instruments used for writing. Broadly speaking, writing can be executed in two distinctly different ways. The script can either be scratched or cut into the surface of the material with a sharp instrument (a stylus, a knife, or the stone cutter's tool) or it can be applied to the surface with a pen (quill, reed, wood, metal) or a brush. Great attention has been paid to the way the pen was trimmed to create different writing styles, and the way the brush and other writing implements were handled and, when not used, kept in good order. Basically two types of ink can be used: carbon ink or iron-gall ink. Carbon ink was used in Egypt as early as 3000 B.C.; it contained no substance injurious to any writing material. Around 300 A.D., with the increasing popularity of parchment, iron gall came into use, but iron-gall ink can fade and eat into the parchment. In addition, ink suitable for the quill damaged the steel pen and it was not before the 1830s that a type of ink was devised that eliminated these difficulties.

Writing Variation into Formal Grammars

G Smith, University of Hong Kong, Hong Kong, China

© 2006 Elsevier Ltd. All rights reserved.

Writing a grammar of a language is already a daunting undertaking, but it is made even more complex by the problem of saying exactly what that 'language' really consists of. It is easy to forget that a language is not actually a thing but an abstraction based on a living, changing reality drawn from the way people choose to communicate. In practice, the boundaries between languages, dialects, and sociolects are notoriously fuzzy. A famous comment attributed to Max Weinreich defines a language as "a dialect with an army and a navy," thus drawing attention to the social and political factors that need to be considered in addition to purely linguistic concerns. Often one variety is elevated to the status of a standard and is generally considered to be the 'correct' form, but this choice may not be based on rational criteria and it is often the variety spoken nearest to a country's capital city that is chosen. In addition, a variety's status as a standard then shapes speakers' perceptions of other varieties, often leading to a judgment that they are incorrect or substandard.

Even when boundaries between dialects and languages can be drawn in a reasonably satisfactory manner, there is variation along a number of dimensions to be taken into consideration. Detailed sociolinguistic studies in the past few decades have added a great deal to our knowledge of different variants in specific geographical locations and among different socio-economic strata. Even within standard varieties, situational factors such as degree of formality have a huge effect on the actual forms produced, especially when social stratification is reinforced by different linguistic means of marking status relationships. Gender and ethnicity also have a role in selection from a pool of available variants. Dealing with these in grammars therefore represents a formidable challenge, and any attempt at a formal grammar is bound to be something of a compromise. These difficulties may be more or less acute depending on the language in question and the type of grammar that is being attempted. Some of the problems arising from variability are considered here with reference to the writing of grammars of Cantonese (Yue Chinese), English, Tok Pisin, and some other languages.

According to the currently accepted classification, Cantonese belongs to the Yue branch of the Sino-Tibetan family. It is spoken by some 70 million people in Hong Kong and south China as well as by smaller but still significant numbers of speakers in Chinatowns worldwide. With such an impressive number of speakers and geographical range, it may appear surprising that it was only a few years ago that the first comprehensive grammar of Cantonese appeared (Matthews and Yip, 1994). This has a lot to do with questions of boundaries and definition. The term 'Chinese' is notoriously hard to pin down, referring to ethnic and racial as well as linguistic entities. The 'Chinese language' as traditionally conceived is a monumental family of related varieties bound together by a long shared history and a common writing system. The national language of the People's Republic of China, Mandarin or Putonghua, is often used synonymously with 'Chinese,' and other varieties spoken in different parts of the country are traditionally termed 'dialects' as a measure of their distance from this standard. However, varieties such as Cantonese are clearly so different in phonology and grammar from Putonghua that the two are mutually unintelligible, and there is no doubt that separate language status is indicated on purely linguistic grounds. However, political factors such as national unity are obviously relevant here, and Cantonese, lacking an army and a navy, seems destined for a second-class 'dialect' status.

The relationship among Chinese languages is further complicated by the fact that many speakers of different languages nevertheless use the same Standard Written Chinese for literacy purposes. This written standard has an extremely long tradition, apparently going back to the first standard based on the classical literary language in the Zhou Dynasty around the 1st millennium B.C. and then on another based on the vernacular literary language during the Tang Dynasty toward the end of the 1st millennium A.D. (Norman, 1988). It seems that this written standard has always had sufficient prestige to prevent the emergence of competing dialect versions. One result of the adoption by Cantonese speakers of a normative written standard based on a different variety is that they have to accommodate to a written register quite different from the spoken form. This has, in turn, led to high and low registers of spoken Cantonese, the former much closer to the written standard and the latter the language of unmonitored informal speech.

Because there is no agreement on the form of Cantonese characters, or even whether such written forms are legitimate, Matthews and Yip took as their starting point the spoken Cantonese of people in Hong Kong. With the authors' fruitful combination of native speaker intuition and skilful linguistic analysis, the issue of variability was taken up head-on by the authors. No fewer than eight phonological

changes in progress are described (Matthews and Yip, 1994: 29), such as the apparent merging of the [n] and [l] phonemes, leading, for example, to apparently free variation between *néih* and *léih* (你) as the second-person singular pronoun. In addition to describing grammatical variability, they also paid attention to what is appropriate in certain situations, in various contexts and at various levels of formality. Although Cantonese speakers tend to have fairly definite views on 'correct' pronunciation and may stigmatize innovations as 'lazy sounds,' there is not a strong tradition of prescription of grammatical forms or a long history of scholarship in a written variety of Cantonese, so the flexible approach of Matthews and Yip was more successful than a more rigid description of grammaticality might have been.

The English language, like Chinese, has a long and eminent tradition of study. The history of English as it emerged from the Germanic branch of Indo-European under the successive influence of Nordic languages and French and then Latin and Greek scholarship is well documented. In recent centuries, standardization through dictionaries and grammars has provided a written authority for the legitimacy of the standard, predictably based on the variety spoken around the capital, London. The prescriptive force of these works has been reinforced through an education system in which a definitive description of forms that are 'correct' or grammatical is usually contrasted with forms that are 'incorrect' and unacceptable. Founded on the received wisdom of prescriptive grammars, pedagogical grammars aim to make the rules of the system as accessible as possible for teachers and learners.

Standard English dictionaries can indicate some stylistic variation, for example, marking entries as informal, slang, or taboo. Lexis typical of major geographical variants (e.g., US and UK) or less widespread varieties (such as Scottish or New Zealand English) can also be indicated in this way. Some newer dictionaries deal with regional English, such as that of Butler (1990) for Australian English, and many new entries reflect the reality of English as used in this part of the world. The project that spawned this dictionary attempted to give recognition to traditionally neglected regional standards, and it is now being extended to other regions, such as southeast Asia. However, published grammars have traditionally been perceived as something solid and enduring and, if not prescriptive, then at least to some degree definitive; and variability can easily be under-emphasized in these works due to pragmatic concerns.

One problem with published dictionaries and grammars toward the prescriptive end of the spectrum, however, is that they inevitably become victims of changes in progress. Many of the words in older dictionaries are now archaic or obsolete, and even grammatical constructions that sounded correct a century ago may now appear affected or pedantic. A descriptive grammar, on the other hand, is less concerned with contrived or constructed examples or with distinguishing the 'correct' from the 'incorrect.' These grammars, like smaller-scale sociolinguistic studies, are firmly rooted in empirical data collected from genuine communicative events. Nevertheless, the ghost of prescriptivism may occasionally come back to haunt them because they have to deal not only with the reality depicted by the study data but with popular perceptions of what is 'right' and 'wrong.' Maidment (1994), for example, described the 'Disgusted of Tunbridge Wells' effect, in which the products of grammatical variation and change are liable to be seen as incorrect and slovenly. In fact, many nonstandard British varieties of English have often been popularly viewed, even by their speakers, as incorrect or lazy versions of the standard.

This situation is even more extreme in the case of pidginized or creolized varieties that have often been treated as defective or incompletely acquired forms of the lexifier language (i.e., the language that provides the majority of the words). Pidgins and creoles are the products of language contact, in which elements of the lexis and grammars of two or more languages combine and may stabilize to produce a new contact variety. There is still considerable debate about the exact nature of these contact languages, but one common feature is the hostility with which they have been viewed, especially by speakers of the lexifier language. It has also led to a self-deprecating view by the speakers themselves that their language is substandard and illegitimate, as seen, for example, in the adoption of the name Broken (from *broken English*) for Torres Strait Creole spoken in northern Australia (Shnukal, 1988). Speakers of creoles may also be part of a speech community in which standard forms of the lexifier languages are spoken alongside it; and whereas the basal form of the creole and the standard language may not be mutually intelligible, a continuum of forms may develop between these extremes. Such postcreole continua have been described in societies such as Jamaica and Guyana, where many intermediate grammatical and lexical forms exist between the creole and Standard English. Speakers typically have a range of competence in different varieties or lects, the exact one chosen for communication being determined by situational factors such as who the person is speaking to.

My own work on Tok Pisin, the expanded English-lexifier pidgin/creole of Papua New Guinea, which is now the *de facto* national language, took as its focus

the effect of young people on the language (Smith, 2002). This contrasts with studies that take as their starting point the speech of older competent speakers as the definitive variety. Variation in the speech of younger people comes from a number of directions. First, those who are speaking the language as a first language use it fluently in a wider variety of situations than those who use it as a second language. Some consequences of this are phonological reduction, with its attendant effect on morphology, and grammaticalization due to reinterpretation of forms in discourse. There is also the substrate effect of other languages spoken by those who use Tok Pisin as a second language. These may be difficult to pinpoint due to the large number of other languages spoken, but they nevertheless have an effect. One language that is having a profound influence on Tok Pisin is the lexifier, English, which is now in renewed contact with the pidgin after several decades of independent development. Large-scale borrowing of lexical items is now taking place as more children grow up fluent in Tok Pisin and educated through the medium of English. In describing the language, therefore, it is important to specify in illustrative examples who is speaking, in what situation, and various other factors about the speakers, such as place of residence, education level, and other languages used within the household.

Dealing with unwritten languages represents an even tougher challenge in the absence of established written norms and standards. Such languages may not have been previously the subject of academic study and may lack even a basic orthography, so here the fieldworker's initial task is clearly descriptive. Even in small-scale societies, inherent variation is a factor that can not be ignored. Nagy's (2001) work on the minority Romance language Faetar (Franco-Provençal) in southern Italy is one rather successful attempt to write variation into the description of the grammar of such a language. She codified various factors about speakers used as informants and was careful to make this information available when dealing with example utterances. A number of variables were kept in mind when producing the grammar, such as the nature of the data used (e.g., elicited vs. naturalistic); age, sex, and occupation of the speaker; and social situation in which a speech act was embedded.

An area with many unstudied languages is Melanesia, well known for its extreme linguistic diversity. Large numbers of languages are typically spoken by only a few hundred people. Many of the 1000 or so languages in this area are relatively unknown, and even basic facts about their phonology and typology may not be established. Moreover, chains of dialects may extend for a considerable distance from village to village, making it unclear where language boundaries might reasonably be drawn. These factors alone represent a formidable challenge to field linguists, and taking variation into consideration has consequently been given low priority in many studies. However, some attempts have been made.

A grammar from the Melanesian country of Vanuatu that has tackled the issue of variation is Crowley's (1999) study of Erromangan (Sie). In it, he examined in detail the variation, for example, between the voiceless fricatives [s] and [h]. At first, this appeared to be a geographical issue, with variant phonemes separated by a north-south isogloss, but further data showed that both variants were produced by a variety of people in different locations and situations in apparently random variation. It thus represents a change in progress – an intermediate stage in a shift from [s] to [h] – and the grammar must somehow find a way of describing this phonemic system in flux. The interesting factor relating to this particular phone pair is that contrast is maintained in ecclesiastical written sources, in which words spoken with [h] are nevertheless rendered with [s] in the written form, thus fossilizing in writing an obsolescent contrast. In a similar way, Dorothy Jauncey's (1997) grammar of Tamambo (another Austronesian language of Vanuatu) tried to report accurately the social constraints governing the alternation among [g], [k], and a voiced velar fricative in intervocalic contexts. In Papua New Guinea, there are, according to the latest *Ethnologue* (Grimes, 2000), between 800 and 900 languages, many poorly known, and some pioneering fieldworkers are currently grappling with similar issues.

Thus, variability represents a challenge to linguistic description that can no longer be left at the periphery. Prescriptive grammars may have a useful role, but the recording and analysis of uncontrived communicative events in naturalistic contexts has come to the fore as the primary data for linguistic study. So, linguistic variation and change must be taken into consideration in any grammatical account that claims to represent the reality of language use.

Wundt, Wilhelm (1832–1920)

E Schröger, University of Leipzig, Leipzig, Germany
J P Rauschecker, Georgetown University School of Medicine, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Wilhelm Wundt was born on August 16, 1832, in Neckarau (close to Mannheim, Germany). In 1851, he obtained his diploma from secondary school, qualifying for university matriculation. In the same year, he started to study medicine at the University of Tübingen. He continued his studies at the University of Heidelberg in 1852, passed his state exams in medicine in 1855, and earned his doctorate in medicine in 1856. His doctoral thesis, titled *Untersuchungen über das Verhalten der Nerven in entzündeten und degenerierten Organen*, was about the role of neurons in inflammatory processes. For one semester he performed research in Berlin with the famous physiologists Johannes Müller and Emil Heinrich du Bois-Reymond. In 1857, he obtained his university lecture qualification (*Habilitation*). Between 1858 and 1863, he was assistant professor to the most influential physiologist of his time, Hermann von Helmholtz, in Heidelberg, where he was appointed adjunct professor for anthropology and medical psychology in 1864. Interestingly, he also engaged in politics from 1864 to 1868; he was a member in the second chamber of the parliament of Baden for the liberal party (*Badische Fortschrittspartei*). He resigned from politics because it began to take too much time away from his scientific life. He got married in 1872 and moved to the University of Zürich in 1874 as professor for inductive philosophy. Finally, he accepted an offer of a professorship for philosophy at the University of Leipzig in 1875, where he was active until 1917. He died on August 31, 1920, in Großbothen, close to Leipzig.

In 1879, he founded the world's first Institute for Experimental Psychology, initially as a private institute, which was approved by the university as an official institute in 1883 with its own budget. Wundt was rector of Leipzig University from 1889 to 1890 and was awarded honorary citizenship of Leipzig in 1902. He had two daughters and one son. His daughter Eleonore, who was his secretary and assistant, compiled his bibliography listing more than 500 publications.

Wundt can be regarded as the father of modern psychology. Among the first members of the newly established institute were Granville Stanley Hall (1844–1924; president of Clark University in Worcester, MA, and founder of the American Psychological Association), James McKeen Cattell (1860–1944; director of the Psychological Institute of Columbia University, New York), Hugo Münsterberg (1863–1916; professor for experimental psychology at Harvard University at the same time as William James), and Emil Kraepelin (1856–1926; director of the Clinic for Psychiatry (later the Max Planck Institute for Psychiatry) in Munich). He supervised 184 dissertations (60 from foreign doctoral students and 18 from the United States). His focus was on

His daughter Eleonore, who was his secretary and assistant, compiled his bibliography listing more than 500 publications.

Wundt can be regarded as the father of modern psychology. Among the first members of the newly established institute were Granville Stanley Hall (1844–1924; president of Clark University in Worcester, MA, and founder of the American Psychological Association), James McKeen Cattell (1860–1944; director of the Psychological Institute of Columbia University, New York), Hugo Münsterberg (1863–1916; professor for experimental psychology at Harvard University at the same time as William James), and Emil Kraepelin (1856–1926; director of the Clinic for Psychiatry (later the Max Planck Institute for Psychiatry) in Munich). He supervised 184 dissertations (60 from foreign doctoral students and 18 from the United States). His focus was on

experimental psychology based on Fechner's psychophysics and reaction time measurements. His opus magnum was *Grundzüge der physiologischen Psychologie* (*Foundations of physiological psychology*) – the first edition published in 1874 comprising 870 pages and the sixth edition published between 1908 and 1911 comprising three volumes with 2327 pages – which established the experimental approach for psychology.

However, his second branch was the so-called *Völkerpsychologie*, supplementing the experimental approach with a nonexperimental approach to adequately investigate phenomena of social psychology, such as language, myth, and custom. According to his view, one gets insight about the psychological principles underlying these faculties by studying their output. He regarded the role of language as special because it is an entry point to understand social and cultural behavior. In fact, he was rather influential for the psychology of language and psycholinguistics; for example, the influential Leonard Bloomfield based his linguistic textbook published in 1914 on Wundtian psychology. According to Wundt, the mental sentence ('as an inner psychological construction') guides the unfolding speech and should therefore be regarded as the unit of language. That is, the sentence is not just a concatenation of words and sounds. On the contrary, sounds, words, the rules of grammar, etc., all have their meaning only in relation to the underlying mental sentence. His book *Logik* (1883) presents a model of syntactic structure, namely the tree diagram of syntax. Language starts with S (the sentence) at the top, and selective attention separates the subject (the focus or figure) from the predicate (the ground), and so on. In the volume *Die Sprache* (*Language*, 1911), he argued in favor of the cognitive level of language operating in a top-down manner. His psycholinguistic work was continued by Ottmar Dittrich, who headed the group on phonetics and psychology of language at the University of Leipzig.

X-Bar Theory

L Haegeman, CNRS, Lille, France

© 2006 Elsevier Ltd. All rights reserved.

Introduction: Outline of X-Bar Theory

The Core Structure

X-bar theory takes its origins in the 1970s and was a central component of the Government and Binding model and the Principles and Parameters model (*see also* **Principles and Parameters Framework of Generative Grammar**) at the end of the 20th century. Both these models had as one of their major leading ideas the hypothesis that the grammar consists of a set of autonomous modules that interact to generate sentences as their output. One such module was, for instance, theta theory, whose task was to ensure that the arguments (essentially, but not exclusively, NPs) in a sentence were associated with a predicate and to express a particular thematic role such as AGENT, PATIENT, LOCATION. (*see* **Thematic Structure; Argument Structure**). Another module was case theory, which served to ensure that noun phrases were associated with the appropriate case (though presence of case did not need to correspond to morphological case marking). A third module is the so called Binding theory (*see* **Binding Theory**), which regulates co-reference relations between nominal expressions in a sentence (reflexives, pronouns, noun phrases). The module of the grammar referred to as X-bar theory regulates phrase structure, that is the internal organization of constituents of a clause (*see* **Constituent Structure**).

X-bar theory formalizes the insight that sentences are not merely strings of words but that the words that compose the sentence are grouped in larger units, called phrases. The goal of X-bar theory is to offer a uniform format for all such phrases in the sentence. The same format applies to the sentence itself, the maximal constituent under analysis. The basis for the X-bar format is found in Chomsky's (1970) "Remarks on nominalization," one of whose aims was to capture the relation between a deverbal noun such as *analysis* and the semantically related verb (*analyze*), without the need to postulate that a deverbal noun phrase such as *John's analysis of the problems* is underlyingly a full fledged sentence (*John has analyzed the problems*) containing the related verb (i.e., *analyze*).

It is a traditional assumption that phrasal constituents can be characterized in terms of the properties of one core component that is identified as the head of the phrase. For instance, a constituent referred to as a noun phrase (NP) is a phrasal constituent whose head is a noun (1a) (see 'X-bar Theory and the Nominal Projection: NP as DP,' however; *see* **Noun Phrases**), a verb phrase is a constituent headed by a verb (1b), an adjective phrase is headed by an adjective (1c), and a prepositional phrase is headed by a preposition (1d):

(1) a. [$_{NP}$ John's [$_{N}$ analysis] of the problems] was impeccable.
[$_{NP}$ John's [$_{N}$ envy] of his wife] was obvious.
b. John will [$_{VP}$ [$_{V}$ analyze] the problems].
John will always [$_{VP}$ [$_{V}$ envy] his wife].
c. John is [$_{AP}$ [$_{A}$ aware] of the problems].
John is [$_{AP}$ [$_{A}$ envious] of his wife].
d. John is [$_{PP}$ [$_{P}$ against] the death penalty].
John is [$_{PP}$ [$_{P}$ in] the basement].

Formalizing this insight, one core tenet of X-bar theory is that syntactic structure is endocentric: a syntactic constituent is built around a head, which determines the properties of the constituent. For instance, constituents headed by a noun (N) are noun phrases (NPs), and as such, share a number of distributional characteristics.

In the first stages of the generative approaches to phrase structure, a large amount of variation was still allowed for the internal make-up of constituents. For instance, it was common to find representations displaying different types of branching within constituents. In (2a), for instance, the NP *John's analysis* is binary branching: the root node, NP, splits into two branches, one leading the possessive genitive NP *John's* and one leading to the head noun *analysis*. In (2b), the NP *John's analysis of the problems* is ternary branching: three branches lead from the

root NP to the constituents of that NP. In (3a), the VP is binary branching, in (3b) it is ternary branching, and in (3c) the VP is split into four branches. The number of branches that could originate from the root node (the topmost NP, VP, etc.) basically depended on the number of constituents contained in the phrase.

(2) a.

b.

(3) a.

b.

c.

The representations in (2) and in (3) are essentially flat: they lack any information as to the internal relations of the components of the constituents, apart from adjacency relations. For instance, the representations fail to capture the crosscategorical generalization that the PP *of the problems* in the NP in (2b) has a relation to the head N *analysis* similar to the relation between the NP *the problems* and the head V *analyze* in the VP in (3). The PP *of the problems* in (2b) can be said to realize the complement of the N *analysis* in the same way that the NP *the problems* realizes the complement of the verb *analyze* in (3). Nor do the representations above lead one to assume that in (3c) the relation between the verb *analyze* and the NP *the problems* is tighter than that between the verb *analyze* and the adverbial phrase *carefully*, since both are adjacent to the verb. However, it is clear that while an object NP is obligatorily present with a transitive verb such as *analyze*, a manner adverbial is not.

In addition, traditional constituency tests suggest that flat structures such as those above are empirically inadequate. Consider (4a):

(4) a. John's analysis of the problems was less convincing than Mary's Ø.
b. John will analyze the problems with care but Mary will **do so** more casually.

In (4a), ellipsis (represented here by the symbol Ø) has affected the string *analysis of the problems*. It is traditionally assumed that if a particular string of words can be affected by a syntactic operation then this string is a constituent. This suggests that in the NP *John's analysis of the problems*, the head noun *analysis* and its complement, the PP *of the problems*, should form a syntactic constituent that excludes the prenominal genitive *John's*. However, in a ternary branching representation such as (2b), no single node exhaustively dominates the head N *analysis* and the PP complement *of the problems*. The only constituents represented in this structure are (i) the complete NP, *John's analysis of the problems*, and (ii) the three composing constituents, the genitive NP *John's*, the head noun *analysis* and the PP complement *of the problems*. Similar considerations can be put forward to argue that the verb and its object form a constituent. In (3b), the string *analyze the problems* is substituted for by *do so*. Again the substitution does not affect the PP *with care*, suggesting that the head verb and the object should be dominated by one node.

X-bar theory constrains the formation of constituents by imposing a blueprint for possible syntactic structure; it defines what is – and what is not – possible syntactic constituent. Based on considerations of simplicity and on constituency tests such as those briefly illustrated above, the flat structures in (2) and (3), which allow multiple branching patterns, have come to be replaced by a hierarchically organized structure. The universal format for all phrase structure is given in (5a) (Jackendoff, 1977: 17):

(5) a.

In the version of X-bar theory that has gained widespread recognition, all syntactic structure is binary branching (cf. Kayne, 1984): that is to say, syntactic units are built up by combining two constituents, thus creating a new constituent. (In the minimalist approach (Chomsky, 1995), the combination of two constituents to form a new unit is referred to as merging [*see also* **Minimalism**]). The representation

in (5a) rules out any structure in which a syntactic node immediately dominates more than two constituents. Any such structures would have to be reinterpreted in terms of hierarchically organized combinations of two constituents.

A constituent (XP) is built around a head X, of a certain category. There is a biunique relation between a head and a projection: each head is associated with one projection and each projection has a unique head. The head of a projection, designated as X in (5a), is a word or a (possibly abstract) morpheme. The category of the head determines the category of the constituent (but *see* **Mixed Categories**). The complement of a head (YP in [5a]) is a phrase that is also formed according to the X-bar format. The head combines with the complement to form a so-called intermediate projection X′. The complement has a tight relation with the head in that the head determines the number of required complements (if any), and it also determines the particular form of the complement(s). For instance in English, verbs select the category of their complement: *analyze* and *envy* select an NP, *wait* and *rely* selects a PP, etc.; nouns or adjectives, on the other hand, combine with a PP complement and do not combine with an NP complement (**a student English*, **the analysis the problems, *envious his wife, *aware the problems*) (*see also* **Argument Structure**).

The properties of the head of a projection determine the properties of the projection: thus, in the unmarked case, if a constituent is headed by a noun it will be of the category NP (and not, say, VP), and if the head of the NP is singular the number of the NP will be singular. In (5c), the NP contains two nouns, singular *analysis* and plural *problems*. It is the number of the head noun, *analysis*, that determines singular agreement of the containing NP. It is sometimes said that the grammatical features of the head (here [+SG]) percolate to the projection.

(5) b. John's analysis of the problems was/*were convincing.

The projection of a head closes off with the specifier. The projection that dominates the head, the complement(s) and the specifier is the maximal projection. As a first approximation, we can represent the structure of the NP as in (5c). As shown (but see 'The parallelism Between Claude and Nominal Projection' below), the specifier of the NP in (5b) can be realized by the prenominal genitive. Alternative fillers for this specifier position would be the possessive pronoun, the article, and the demonstrative pronoun. Because of their complementary distribution, determiners and prenominal genitive are assumed to occupy the same position (cf. Jackendoff, 1977).

(5) c.

John's	analysis	of the problems
his	analysis	of the problems
the	analysis	of the problems
this	analysis	of the problems

The specifier–head relation is typically a feature-sharing relation in that fillers for a specifier are often seen to agree with the head. Agreement is realized overtly on English demonstratives. In other languages such as French, possessive pronouns as well as articles display agreement in number (and gender) with the head noun.

(5) d.

la	description	des problèmes
the$_{F\text{-}SG}$	*description*$_{F\text{-}SG}$	*of the problems*
les	descriptions	des problèmes
the$_{PL}$	*description*$_{PL}$	*of the problems*
sa	descriptions	des problèmes
his/her$_{F\text{-}SG}$	*description*$_{F\text{-}SG}$	*of the problems*
ses	descriptions	des problèmes
his/her$_{PL}$	*description*$_{PL}$	*of the problems*

A constituent in the specifier of a projection may also have a subject-like relation to the head of the projection. This is illustrated in the examples above: the prenominal genitive *John's* or the possessive pronoun *his* can be argued to refer to the AGENT of the deverbal N *analysis* in (5c). In the French examples (5d), the possessive pronoun *sa/ses* denotes the AGENT of the activity denoted by the N *description*. Specifier or complement are not necessarily realized in the projection, as illustrated by (2a), in which there is no complement to the N. (For a discussion of the specifier of VP see 'The Base Position of the Subject' below).

Phrases differ in terms of the properties of their heads; this variation determines their external distribution. However, the format for their internal organization (5a) is shared by all phrases, regardless of the category of their head. In this way X-bar theory brings out the properties common to phrases of

various categories (NP, VP, etc.) and it offers a framework for expressing crosscategorial generalizations. For instance, as discussed above, the notion complement of is not only relevant to VP but it is a defining property of all constituent types. When particular syntactic operations (essentially movement) generalize across categories, it is expected that they will apply uniformly at the same level of the projection, for instance at the level of the maximal projection (XP) or at the level of the head (X) (cf. Jackendoff, 1977: 17).

For a discussion of the different implementations of X-bar theory see Stuurman (1985: Chap. 1, Sect. 3 and 4), who also shows that equating X-bar theory with the superscripting notation of the American structuralist approach of the 1950s is not justified (Stuurman, 1985: Chap. 1: Sect. 2). For critical evaluation of implementations of X-bar theory see also Kornai and Pullum (1990).

Extending the Core: Adjunction

In addition to the core elements of the projection of the head, syntactic theory must also provide a means for enriching a structure with modifying elements, which, though associated with a particular projection, are nonetheless not essential attributes of that projection. For instance, manner expressions of the type illustrated by the PP *with care* in (3b) and by the adverbial phrase *carefully* in (3c), are not essential attributes of a verb phrase headed by the verb *analyze*. They do not form part of the core VP and they are not selected by the verb: the manner expression associated with a VP headed by the verb *analyze* can be realized by a PP, an adverbial phrase, or even an NP. Such constituents are added to the completed core projection, which has itself been constructed according to (5a). The creation of an extra layer of the projection is achieved by a process referred to as adjunction. Adjunction combines a fully projected constituent with another maximal projection. An adjoined manner constituent can be interpreted as a modifier to the constituent to which it is adjoined. In (6a) the maximal projection of V combines with the maximal projection *very carefully* to form an augmented maximal projection VP.

(6) a.

Observe that in (6a) the combination of VP with the adjunct *very carefully* does not create a new VP. By adding an extra layer, the adjunction extends the core VP consisting of the head and its complement. In (6a) the adjunct is right-adjoined. When adjuncts linearly precede the constituent they modify, they are left-adjoined:

(6) b. John will [$_{VP}$ very carefully [$_{VP}$ analyze the problems]].

The number of adjuncts to a particular projection is not syntactically determined, though processing constraints will *de facto* restrict their actual number. The order of adjunction reflects the semantic closeness of the adjunct to the phrase that it modifies. For instance, in (6c), first the adjunct *completely* is added to the VP *reread the text*. Informally, we can say that the adjunct specifies the domain of application of the action expressed by the verb *reread:* (6c) expresses that the action of rereading affects the complete domain of the object *the text*. In turn, the manner adjunct *very carefully* is adjoined to the output of that first adjunction: *very carefully* applies to the extended VP *completely reread the text*. Hence, *very carefully* will be interpreted as modifying the denotation of the extended VP *completely reread the text*.

(6) c. John will [$_{VP}$ very carefully [$_{VP}$ completely [$_{VP}$ reread the text]]].

Both the syntactic status and the semantic interpretation of adjuncts in syntactic structure has led to a wide range of proposals (see Escribano, 2004). For further discussion of the theoretical status of X-bar theory see also Speas (1990). For discussion of scopal relations between adjuncts see also Cinque (1999), Ernst (2002), and the references cited therein. In the Minimalist framework, Chomsky (1995) distinguishes between two types of merger: so-called Set Merge is the operation that creates the core constituent; Pair Merge adjoins one XP to another one (*see* **Minimalism**).

Applications of X-Bar Theory and Functional Structure

Lexical and Functional Categories

Initially (e.g., Jackendoff, 1977), the X-bar format was essentially formulated to characterize the projection of the lexical categories noun, verb, adjective, and preposition, and functional categories were integrated as specifiers of these lexical projections. As shown in (5c, 5d) above, the determiner was, for instance, taken to realize the specifier of the NP;

auxiliaries were sometimes represented as specifiers of VP. The sentence was either taken to be a combination of NP and VP and not subject to the X-bar format, or alternatively, it was taken to be a projection of the verb with the subject as a specifier of a V projection. In the 1980s, the X-bar format was generalized to capture all syntactic structure, including the sentence (Stowell, 1981; Chomsky, 1986). Moreover, the type of projecting head was extended: the head of a projection could be either lexical (N, V, A, P) or it could be a functional morpheme such as an inflectional element, an auxiliary, a tense particle, or a conjunction (*see also* **Functional Categories**). Lexical heads are at the basis of lexical projections; functional heads project functional projections. (On hybrid categories see Pullum (1991), Corver and van Riemsdijk (2001), and the references cited.) Furthermore, the idea was developed that a lexical projection was always integrated into a dominating functional projection (Grimshaw, 1991).

X-Bar Theory and the Sentence

In the literature, a number of proposals have been formulated for integrating the structure of the clause into the X-bar format. A first fairly comprehensive analysis was elaborated in Jackendoff (1977). What most approaches, from the earliest to the most recent, have in common is that a sentence formed round a lexical verb is seen as essentially an expansion of the projection of that verb. That is to say: the lexical or thematic core of such a sentence is taken to be the VP. For instance, sentence (7a) is taken to have as the core of its projection the verb *analyze*:

(7) a. John will analyze the problems.

But clauses are more than just the projection of a verb. The VP is associated with various morphemes of aspect, time, and modality. For instance, in (7a) the VP built around *analyze* is associated with the modal auxiliary *will*. Functional morphemes head their own projections; these functional projections are again instantiations of the X-bar format. One particular influential proposal (Stowell, 1981; Chomsky, 1986) builds on the assumption that VP is integrated into the clause via the functional head Inflection (abbreviated as I), which takes VP as its complement. The head Inflection may be realized by a tense morpheme, an auxiliary, or an invariant particle. In English, for instance, I(nflection) is filled by the bound tense morpheme, a finite auxiliary or infinitival *to*. I and its complement VP form the intermediate constituent I′. I′ combines with a specifier to form IP. The specifier of IP is the canonical subject position. As can be seen in (7b), the representation of (7a), the subject position is the highest nominal position in the structure. Observe that while in Jackendoff's (1977) proposal the canonical subject position was a specifier of VP, here the subject is associated with the functional projection, IP. Grammatical functions such as 'subject of' or 'object of' are derivative concepts, they are reinterpreted in terms of specific positions in the clause structure. In English, the specifier position of IP is the canonical subject position (see also 'The Base Position of the Subject' below) and the constituent which is the sister of V in V′ is the direct object. For a review of this approach to grammatical functions and the problems it raises, see among others Davies and Dubinsky (2001) and Baker (2001).

(7) b.

In turn, IP is inserted as the complement of the functional head C, which can be realized by a subordinating conjunction.

(7) c.

Each layer of the clause contributes a specific dimension to its interpretation. VP contains information concerning the event and its arguments; IP situates the event in time, specifying aspectual, temporal, and modal dimensions of the state of event/state of affairs denoted by VP. The head C selects a clausal complement: when realized by the conjunction *that*, C selects a finite IP; when C is realized by *for*, its complement is nonfinite. The projection headed by C serves to link the clause (IP) with the context/discourse. The filler of C encodes the illocutionary

force of the sentence, that is, the way the speaker presents the information to his interlocutor. In embedded clauses, *that* introduces a declarative clause; *if* introduces an interrogative clause. In direct questions the finite auxiliary (in I) moves to C to encode illocutionary force:

(7) d.

In (7d), the strikethrough symbol ~~*will*~~ represents the unpronounced copy of the fronted auxiliary *will*. This notation serves to keep track of the derivational history of a constituent: the modal auxiliary originates in I, where it encodes future modality, and it is subsequently fronted to C, where it encodes interrogative force. By means of the unpronounced copy, ~~*will*~~, the original semantic and syntactic relations of a moved constituent are maintained in the representation even after the element has been displaced. In earlier versions of the theory, moved constituents were said to leave a trace (represented by t). The index on the trace (the subscript m in [7e]) encodes the link with the displaced constituent with same index:

(7) e. $[_{CP}\ [_{C'}\ [_{C}\ \text{Will}_m][_{IP}\ [_{NP}\ \text{John}][_{I'}\ [_{I}\ t_m]$
$[_{VP}\ \text{analyze}\ [_{NP}\ \text{the problems}]]]]]]$?

The specifier of CP is typically filled by constituents encoding discourse relations. For instance, in English, an interrogative constituent such as *which problems,* though functioning as the direct object of the verb *analyze* in (8a), will not normally remain in its VP-internal position right-adjacent to V, but it will be moved to the sentence-initial position, where it encodes the scope of the question. This initial position is the specifier of CP (but see 'Functional Structure' below).

(8) a. $*[_{CP}\ [_{C'}\ [_{C}\ \text{Will}][_{IP}\ [_{NP}\ \text{John}][_{I'}\ [_{I}\ \cancel{\text{will}}]$
$[_{VP}\ \text{analyze}\ [_{NP}\ \text{which problems}]]]]]]$?
b. $[_{CP}\ \text{Which problems}\ [_{C'}\ [_{C}\ \text{will}][_{IP}\ [_{NP}\ \text{John}]$
$[_{I'}\ [_{I}\ \cancel{\text{will}}]\ [_{VP}\ \text{analyze}\ [_{NP}$
$\cancel{\text{which problems}}]]]]]]$?

Each of the clausal layers, CP, IP, and VP, is built up according to the same principles of X-bar theory. Syntactic relations are established domain-internally (that is, locally). VP is the thematic domain of the clause; IP is the inflectional domain involved in licensing various properties of the verb (tense, agreement, aspect, modality); CP constitutes the interface with the discourse.

Movement and Structure Preservation

A Positions Versus A′ Positions A distinction is made between so-called A positions (short for argument positions), such as the specifier of IP or the complement of V, which are inherently associated with grammatical functions (subject, direct object), and A′ positions (nonargument positions), such as the specifier of CP, which may host constituents with different grammatical functions. The specifier of IP, for instance, is an A-position: it hosts the subject of the clause and a constituent that occupies that position will have subject properties. As shown by (8b) above and also by (8c–f) below, the initial constituent in a constituent question, which is taken to occupy the specifier of CP, can be associated with a wide range of grammatical functions. The specifier of CP is an A′-position. Movement to an A-position is often referred to as A-movement; movement to an A′-position is A′-movement.

(8) c. To whom will John give the book?
d. When will John analyze the problems?
e. How carefully could John analyze the problems?
f. Why should John analyze this problem?

Types of Movement and Structure Preservation Two types of movement are differentiated: (i) head movement, illustrated by the movement of the modal auxiliary *will* to the position C, and (ii) phrasal movement or XP-movement, in which a complete constituent (a maximal projection) is moved. The movements are structure preserving (Emonds, 1976) in that a head moves to a head position and a phrase moves to a phrasal position, respecting the X-bar format. Head movement can also lead to the formation of complex verbs as found in polysynthetic languages (Baker, 1996).

Head movement is essentially clause-bound. Maximal projections may be moved out of the clause in which they acquire their thematic relations (8g). Such long extraction to the specifier of a higher CP proceeds through the specifier of the lower CP, the so-called escape hatch for movement.

(8) g. $[_{CP}\ \text{To whom did}\ [_{IP}\ \text{you say}$
$[_{CP}\ \cancel{\text{to whom}}\ \text{that}\ [_{IP}\ \text{John will give}$
$\text{it}\ \cancel{\text{to whom}}]]]]$?

Configurational Relations

Relations between the constituents of a clause can be stated configurationally, that is, in terms of the geometry of the tree. One such relation that has been shown to play an important role in syntax is the relation c-command (Reinhart, 1981). A constituent X c-commands a constituent Y if there is a node Z such that Z immediately dominates X and Z also dominates Y. By this definition, the specifier of IP c-commands all the constituents contained in IP: the subject NP in the specifier of IP is immediately dominated by IP, which in turn dominates VP, the VP-internal object, etc. Similarly, the specifier of CP c-commands the constituents of the containing clause, etc. Conversely, a VP-internal object does not c-command the elements in the containing IP (*see also* **Command Relations**).

C-command relations account for various syntactic and semantic relations and for observed subject/object asymmetries. For instance, the subject in the specifier of IP c-commands the constituents of the IP domain, and it is the most prominent NP of that domain. Because of its configurational prominence, the subject functions as the prototypical antecedent for any reflexives and reciprocals in the IP domain (*see also* **Binding Theory**). The subject NP *the students* in (9a) binds the reciprocal *each other* contained in the direct object, the object NP *the students* cannot bind the subject in (9b):

(9) a. The students invited each other's friends to the party.
b. *Each other's friends invited the students to the party.

Similarly, when the subject in the specifier of IP is a negative quantifier, it can license a polarity item in the IP domain, whereas a negative quantifier as an object cannot license a polarity item in the subject position:

(10) a. No one liked anything last night.
b. *Anything pleased no one last night.

X-Bar Theory and the Nominal Projection: NP as DP

This section returns to the projection of the noun. In the same way that the clause is a projection of V embedded in functional projections, the lexical projection of the noun, NP, is embedded in functional projections. In this way, various similarities between nominal projection and clause can be brought to the fore (Abney, 1987).

Specifiers of NP

Initially, the projection of N was taken to be simply NP, with the specifier realized, among other things, by the determiner or by a prenominal genitive NP (see [5c, d]). Jackendoff (1977: 103–104) already points out that such an approach groups together rather different entities, with different semantic functions. It is clear that amalgamating determiners (essentially articles such as *the* or *a,* or demonstratives such as *this*, *that*) with a genitive NP is counter-intuitive. Determiners are one-word functional elements, they belong to a closed class; genitives are full phrases, they are open-class elements that may very well have internal structure; possessive pronouns substitute for full nominal phrases. In the NP *his analysis of the problems,* for instance, the possessive pronoun *his* could replace a genitive such as *the new teacher's*. It seems inappropriate that such widely different units should be treated as identical.

There is also crosslinguistic motivation for not inserting articles and possessors in the same position: in many languages, possessive pronouns and articles cooccur. (11a) is from Italian and (11b) from Catalan:

(11) a. la mia casa
the-FEM-SG *my*-FEM-SG *house*-FEM-SG
'my home'

b. la meva casa
the-FEM-SG *my*-FEM-SG *home*
'my home'

Hungarian offers a further illustration of this point.

(11) c. az en kalap-om
the *I* *hat*-1SG
'my hat'

d. a te kalap-od
the *you* *hat*-2SG
'your hat'

e. a Peter kalap-ja
the *Peter*-NOMINATIVE *hat*-3SG
'Peter's hat'

In (11c–e), the prenominal possessors, whether pronominal (11c) and (11d) or lexical (11e), have a nominative case form, as a subject NP would have in a clause.

The DP Hypothesis

The sentence is an extended projection of VP: it consists of a lexical projection (VP) embedded in a sequence of functional projections (Grimshaw, 1991). Generalizing this hypothesis, it is proposed that projections of lexical heads are always embedded within the projections of functional heads. Thus, in the unmarked case, the projection of a noun head should not be expected to surface as a bare NP projection of the lexical head N, but the projection of the lexical

head N will also have to be inserted into a functional domain. Pursuing this path, the nominal projection has been reinterpreted as consisting of a lexical domain headed by N dominated by a functional domain headed by the determiner (Abney, 1987). It is proposed that in order to function as an argument, an NP must be embedded in a DP. Thus a structure along the lines of (12a) is replaced by one like (12b):

(12) a.

b.

See, however, Tomioka (2003) for a proposal that bare NPs may be arguments.

The Parallelism between Clause and Nominal Projection

This revision of the nominal projection leads to a closer similarity between the projection of the noun and the clause, and many parallelisms are found across the two domains. For instance, in the clause, the domain of C is associated with discourse related effects (topicalization, focalization, and illocutionary force). Similarly, the semantic function of D can be said to establish reference (Longobardi, 1994), that is, a relation between the NP and a discourse referent.

DP Internal Movement: The Case of Modern Greek In the same way that constituents may move within the clausal domain, and may be extracted from it, movement can be seen to apply within the nominal domain, and in some cases extractions from the nominal domain are also possible. Horrocks and Stavrou (1987: 86) discuss examples such as the following from Modern Greek:

(13) a. to vivlio tu Chomsky
the book *the*-GEN *Chomsky*
'the book by Chomsky'
a′. tu Chomsky to vivlio
b. i kritiki tu vivliu
the review *the*-GEN *book*-GEN
'the review of the book'
b′. tu vivliu i kritiki
c. to endhiaferon ya to arthro afto
the interest *about the article this*
'the interest of this article'
c′. ya to arthro afto to endhiaferon

In each of the pairs in (13), the constituent following the head N in the nonprimed example is fronted to a pre-N position in its primed counterpart. The interpretive effect of such fronting is that of focalizing. Horrocks and Stavrou (1987: 86) say, "All this is obviously reminiscent of the fronting of constituents that takes place in sentences for the purpose of bringing a particular constituent into prominence." The application of focusing in the domain of the sentence is illustrated in (14), in which the indirect object *tis Afrodhitis* or the direct object *to vravrio* ('the prize') can be fronted for focalizing effects. Horrocks and Stavrou (1987) show that in the clause focalization has the properties of A′-movement (cf. 'A-positions Versus A′-positions' above).

(14) a. Edhose to vravio tis Afrodhitis.
gave-3SG *the prize* *the*-GEN *Aphrodite*-GEN
'He gave the prize to Aphrodite.'
b. Tis Afrodhitis edhose to vravio.
c. To vravio edhose tis Afrodhitis.

The parallelism between interrogative clauses and interrogative DPs in Greek strengthens the assumption that DP is to NP what CP is to VP. (15), from Horrocks and Stavrou (1987: 89), illustrates the interaction between clausal movement and DP-internal movement. Example (15a) corresponds most closely to a sentence with minimal movement; in (15b), the interrogative genitive *tinos* ('whose') has been fronted DP-internally; in (15c), the interrogative genitive *tinos* is extracted and fronted to the specifier of the matrix CP. In (15d) and (15e), movement has affected the full DP. In the former case, movement has not applied DP internally, in the latter it has. Strikethrough shows the derivational history of the moved constituents.

(15) a. Mu ipes [$_{CP}$ pos dhiavases
me-GEN *said*-2SG *that read*-2SG
[$_{DP}$ to vivlio tinos]].
the book who-GEN
'You told me you read whose book?'
b. Mu ipes [$_{CP}$ pos dhiavases [tinos to vivlio ~~tinos~~]].
c. [$_{CP}$ [Tinos] mu ipes [$_{CP}$ ~~tinos~~ pos dhiavases
[$_{DP}$ ~~tinos~~ to vivlio ~~tinos~~]]]?

d. [$_{CP}$ [$_{DP}$ To vivlio tinos] mu ipes [$_{CP}$ ~~to vivlio tinos~~ pos dhiavases ~~to vivlio tinos~~]]?
e. [$_{CP}$ [$_{DP}$ Tinos to vivlio ~~tinos~~] mu ipes [$_{CP}$ ~~tinos to vivlio tinos~~ pos dhiavases ~~tinos to vivlio tinos~~]]?

DP Internal Movement: An Illustration from English The evidence that the specifier of the DP projection can be a landing site for movement in the nominal domain can be reproduced for English. (For ease of presentation we do not represent the original positions by strikethrough here).

(16) a. [$_{CP}$ [$_{AP}$ How important] [$_{C}$ is] [$_{IP}$ this decision]]?
b. [$_{CP}$ [$_{DP}$ [$_{AP}$ How important] a decision] [$_{C}$ is] [$_{IP}$ this]]?
c. This is [$_{DP}$ a [$_{AP}$ very important] decision].

Example (16a) illustrates a root question derived by movement of the interrogative AP, *how important,* to the specifier of CP and movement of the copula to C. Example (16b) is a root question in which the preposed constituent is a DP, *how important a decision*. Inside the fronted DP *how important a decision*, the interrogative AP (*how important*) precedes the indefinite article *a*. The prearticle position of the adjective *important* is not the unmarked position of a prenominal adjective in English (16c). Example (16b) illustrates a DP-internal application of movement of an interrogative constituent *how important* targeting the specifier position of DP. This again suggests an analogy between the specifier of DP and the specifier of CP.

Just as specifier of CP may host noninterrogative constituents introduced by *so* (17), the specifier of DP may host noninterrogative constituents introduced by *so*. This fronted DP in (17) exhibits leftward DP-internal movement of the AP *so vivid*. The landing-site of this movement is to the immediate left of D, i.e., the specifier of DP.

(17) [$_{CP}$ [$_{DP}$ [$_{AP}$ So vivid] a picture] does [$_{IP}$ this program draw of the situation of these animals that the reader wants to react immediately]].

DP Internal Movement: Possessors in Hungarian As shown by Szabolcsi (1994), Hungarian offers further confirmation for aligning the D node in the nominal projection with C in the clause. The Hungarian prenominal possessor may occupy two positions. It either follows the determiner, in which case it has nominative case (18a), or it precedes the determiner, in which case it has dative case (18b).

(18) a. a Mari kalap-ja
the *Mari*-NOM *hat*-3SG

b. Mari-nak a kalap-ja
Mari-DAT *the* *hat*-3SG

It seems plausible that *Marinak* in (18b) occupies the specifier position of DP.

(18) c.

In later work, it was proposed that additional functional projections be distinguished, aligning the clausal IP projection with nominal IP projections related to nominal inflection (e.g., Ritter, 1991).

X-Bar Theory and the Internal Make-up of VP

The Base Position of the Subject

In the original proposals for the clause structure of English (and similar SVO languages), the subject NP was inserted in a VP-external position c--commanding the clausal domain (see, for instance, Jackendoff, 1977). Since the 1980s, it has been proposed that the base position of the subject is VP-internal (Stowell, 1983; Kitagawa, 1986; Sportiche, 1988; Kuroda, 1988; Koopman and Sportiche, 1991; Huang, 1993). This assumption is motivated by the hypothesis that syntactic relations are established locally. The verb has a thematic relation with the subject. If thematic relations are subject to a locality restriction, the thematic relation between the subject and the verb must be established locally, i.e., within the domain of the verb, VP. Thus, the subject should establish its relation with V within VP. To make this conclusion compatible with the observed VP-external position of the subject, it is proposed that the subject starts out (or is merged in Minimalist terminology) as the specifier of VP and that it moves to its canonical, VP-external position, the specifier position of IP. In (19a), the subject NP *John* is inserted as the specifier of the projection of the V, *analyze*. The VP is combined with the functional head I, forming I′ (19b), this makes available a specifier position for the projection of I (19c), and the subject *John* will move out of the VP into that position:

(19) a. [$_{VP}$ John [$_{V'}$ analyze [$_{DP}$ the problems]]]
b. [$_{I'}$ will [$_{VP}$ John [$_{V'}$ analyze [$_{DP}$ the problems]]]]
c. [$_{IP}$ John [$_{I'}$ will [$_{VP}$ ~~John~~ [$_{V'}$ analyze [$_{DP}$ the problems]]]]].

In (19a), the verb *analyze* has two arguments, both VP-internal: the THEME, *the problems*, and the AGENT *John*. By a subsequent (A)-movement operation, the subject externalizes (19c).

Various types of empirical support have been put forward for the idea that the subject originates in the specifier of the VP (see Sportiche, 1988; Kuroda, 1988; Koopman and Sportiche, 1991; and for a survey also McCloskey, 1997). One piece of evidence is provided by existential structures that contain both an expletive subject (*there* in English) and a real or logical subject. Example (20a) is an illustration from English. Assuming a VP-internal base position for the subject, one might propose that such examples are the result of a failure of the subject to leave its base position and move to the specifier of IP. In such cases, the canonical subject position hosts an expletive pronoun (cf. McCloskey, 1997 and the references cited). In (20a), the subject NP *three students* remains VP-internally, and an expletive subject *there* fills the canonical subject position, the specifier of IP. In (20b), on the other hand, the subject has moved to the specifier of IP, leaving a copy in the VP.

(20) a. [$_{IP}$ There are [$_{VP}$ three students [$_{V'}$ analyzing the data]]].
b. [$_{IP}$ Three students are [$_{VP}$ ~~three students~~ [$_{V'}$ analyzing the data]]].

While the English existential construction is restricted to sentences containing *be* and a number of (unaccusative) verbs, other languages allow for this construction with all active transitive verbs (for classifications of verbs, *see also* **Ergativity**). The Icelandic examples in (21) are from McCloskey (1997: 215).

(21) a. Þaδ grefur kona gröf í garδinum.
there digs a-woman a-grave in garden-the
'There digs a woman a grave in the garden.'

b. Þaδ hefur einhver borδaδ epli.
there has someone eaten an-apple
'There has someone eaten an apple.'
(McCloskey, 1997: 215, his (43))

The Position of the Inflected Verb

The position of the inflected verb varies crosslinguistically. For instance, while in English the verb is obligatorily adjacent to its object in VP and follows left-adjoined adverbial constituents, in French the inflected verb precedes such left-adjoined adverbials:

(22) a. John always discusses problems.
b. Jean discute toujours les problèmes.
Jean discusses always the problems

It is assumed that adverbial adjuncts (*always, toujours)* occupy the same position in both languages. To account for the crosslinguistic difference in distribution of the finite verb and the adjuncts, it is proposed that the verb remains in VP in English but that in French it moves to the I position. This variation in movement of the verb is sometimes related to the nature of the verbal paradigm (see Emonds, 1978; Roberts, 1985; Pollock, 1989), though it remains unclear to what extent overt morphology can be seen as the trigger for movement.

(23) a. [$_{CP}$[$_{IP}$ [$_{NP}$ John][$_{I'}$ [$_{I}$] [$_{VP}$ always [$_{VP}$ discusses [$_{NP}$ problems]]]]]].
b. [$_{CP}$[$_{IP}$ [$_{NP}$ Jean][$_{I'}$ [$_{I}$ discute] [$_{VP}$ toujours [$_{VP}$ ~~discute~~ [$_{NP}$ les problèmes]]]]]].

For a different view on the distribution of VP complements and adjuncts in French and in English see Miller (1999) in the HPSG framework.

VSO Languages

The hypothesis that the subject originates in VP ('The Base Position of the Subject' above), coupled with the proposal that the verb may move to I ('The Position of the Inflected Verb' above), leads to an account for the observed variation in word order between so-called SVO languages such as English and French and the so-called VSO languages such as Arabic or the Celtic languages (see Carnie and Guilfoyle, 2000). For instance, in Irish (24) the verb precedes both the subject (*siad*, 'they') and the object (*teach,* 'house') (McCloskey, 1997: 210, his (20)).

(24) Cheannaigh siad
bought they-NOM
teach ar an bhaile mhór anuraidh.
house on the town big last-year
'They bought a house in town last year'

The VSO pattern can be derived by assuming that the subject is VP-internal and the verb moves to I, ending up to the left of the subject. For VSO languages, see Travis (2001) and the references cited therein. For SOV languages, see 'Directionality' below (*see also* **Word Order and Linearization**).

Event Structure and VP

It has been proposed that V should be decomposed into more elementary components, each formed according to the X-bar format. At the origin of this proposal is the double object construction (25a) and the problems it raises for the binary branching

approach. If multiple branching is admitted, then one might envisage a structure such as (25b) to represent a VP containing an indirect object and a direct object. (For ease of presentation, the representation leaves aside the subject in VP hypothesis).

(25) a. John gave Mary the books.
b.

However, in a binary branching model, this representation has to be reinterpreted (Kayne, 1984). Scopal relations also cast doubt on the flat representation. In (25b), indirect object and direct object are in a mutual c-command relation (see 'Configurational Relations' above for the definition of c-command): the indirect object c-commands the direct object and vice versa. C-command relations are used to account for the licensing of polarity items: a polarity item such as *anyone* or *anything*, for instance, can be licensed by a c-commanding negative constituent (cf. discussion of [10]). In double object constructions, an indirect object can license a direct object polarity item as in (26a), but the reverse is not possible (26b):

(26) a. John gave none of the students anything.
b. *John gave any of the students nothing.

If polarity licensing depends on the c-command relation, the observed asymmetry in the double object construction suggests that the indirect object c-commands the direct object but that the direct object must not c-command the indirect object. Various authors have proposed ways of expressing the VP-internal syntactic relations (Larson, 1988; Hale and Keyser, 2002). In one proposal, a ditransitive verb such as *give* is reanalyzed as a complex causative verb, roughly corresponding to 'cause to get' (*see* **Complex Predicates**). The causative component is represented by an abstract verb, little v, whose specifier is the CAUSER argument (the AGENT of *give*). The abstract causative little v projects its own vP, respecting the X-bar format; v takes as its complement a projection of the V *give*: (cf. Hale and Keyser, 2002).

(27)

The lower V *give* moves to v to form transitive *give*. Similarly, inchoative *open* could be decomposed into a complex verb containing an abstract inchoative head ('become') and an adjectival predicate (*open*); transitive *open* could be decomposed in terms of a complex causative verb ('cause to become open'). The complex event structure of the VP has been the focus of a great deal of research (see especially Hale and Keyser, 2002 and the references cited therein).

Developments, Discussions

There has been a tendency, already illustrated in 'X-bar Theory and the Nominal Projection: NP as DP' and 'X-bar Theory and the Internal Make-up of VP' above, to decompose syntactic units in terms of more articulated structure. At each stage, the novel structures instantiate the X-bar format. Some additional innovations of this type are illustrated in this section (see also Baltin and Collins, 2001; Haegeman, 1997). On the other hand, there is also an attempt to reduce the complexity of structure and to pare down the contents of X-bar theory to the minimum. This is briefly discussed in 'Some Alternative Views' below.

Functional Structure

The number and nature of the functional heads in the IP and the CP domain has come under closer scrutiny in recent years. Based on work by Pollock (1989), it has been argued that IP is not a homogeneous domain with a unique functional head. The head I has been split into a number of specialized functional heads. Each such head projects according to the X-bar format. One might postulate, for instance, a projection of agreement, tense, mood, and aspect. It has also been proposed that sentential negation be associated with a specialized functional projection (NegP).

Similarly, given that the CP domain may contain a range of fronted constituents, each with their own specialized discourse functions (interrogative constituents, relative constituents, exclamative constituents, topicalized constituents, negative constituents, focused constituents, scene setting adjuncts, etc.) and that some of these may co-occur, CP has been decomposed in a number of specialized projections, such as TopP (topic projection), FocP (focus projection) (Rizzi, 1997).

The status of functional categories in syntactic theory is much debated and many controversies remain. There is as yet no consensus about how many such projections there are, and whether they

are universally instantiated in a given structure, even when no overt material is associated with them. An alternative to such highly articulated structures is to replace discrete functional projections of specialized heads by a structure in which one functional head is enriched with multiple distinct (hierarchically organized) features. If a particular head is associated with a cluster of specialized features, each such feature could license a specifier, giving rise to layered specifiers (cf. Chomsky, 1995). This proposal would reduce the need for postulating a large range of functional projections, but it would entail giving up the single-specifier hypothesis.

There is also ongoing debate as to whether the functional projections in the IP domain have a universally determined hierarchy (cf. Cinque, 1999 and the references cited). Agreement projections, in which agreement relations between a nominal projection and the matching inflectional morphology of a verb are licensed, have come under scrutiny. In the framework of the Minimalist approach, Chomsky (1995) argues that functional projections should be projected exclusively on the basis of interpretable features. Agreement features of a verb are uninterpretable in the sense that they reduplicate the agreement features on the matching nominal projection and do not themselves have semantic impact. If such uninterpretable formal features cannot be at the basis of a projection, then one can no longer postulate agreement projections in the clausal domain. The relevant agreement features will have to be instantiated on another functional head (for instance, Tense). Others take an intermediate position and postulate that depending on their specific morphology, languages may or may not have a separate agreement projection to encode subject agreement features (cf. Speas, 1990).

In the Minimalist approach, the status of the intermediate projection (X′) is also being reconsidered (cf. bare phrase structure, Chomsky, 1995).

The Status of Adjunction

The theoretical status of adjunction as a structure-building mechanism (see 'Extending the Core: Adjunction' above) has also come under scrutiny. Some propose that adjunction be entirely eliminated from the theory (Kayne, 1994; Cinque, 1999). What appear to be adjoined constituents are reanalyzed as specifiers of specialized functional heads. Cinque (1999) takes this proposal one step further and elaborates a clause structure that is a hierarchically organized sequence of functional heads, each with a specific semantic function. The head of the projection hosts free or bound morphemes encoding concepts of modality, tense, aspect (progressive, perfective), etc. The specifiers of the relevant projections host adverbial adjuncts that encode matching concepts.

Directionality

Languages vary with respect to the order in which verb and objects are linearized: English and French are SVO languages: in the unmarked word order, the verb precedes the object, Japanese is an SOV language: the verb follows the object:

(28) a. John hit Mary.
b. Jean frappait Marie.
Jean hit-PAST Marie
c. John ga Mary o but-ta.
John –NOM Mary –ACC hit-past
'John hit Mary.' (Kuno, 1973).

The X-bar format determines the hierarchical relations between the components of a constituent, but it does not determine their linear order. One option to account for the observed OV/VO variation is to postulate crosslinguistic variation in the head-complement relation: English complements would follow the head (29a), while in Japanese the complements of V would precede V (29b).

(29) a.

b.

In contrast, the universal base hypothesis postulates that the format in (5a) is universal, and allows for no variation in directionality: specifiers precede the head and complements follow the head (Kayne, 1994). In such a framework, a surface OV order would be generated by leftward movement of the object from its base position to the right of V. This approach will either imply postulating additional functional projections whose specifiers can host the moved constituents or, alternatively, heads will have to be allowed to have multiple specifiers to host the moved constituents.

The issue of directionality also arises with respect to adjunction. Adverbial adjuncts can be seen to precede or follow the verb. According to some, the direction of adjunction is free (cf. 'Lexical and Functional Categories' above). According to others, though, adjunction must be restricted to left adjunction only. In this view all adverbial adjuncts would be adjoined to the left of the VP. Adjuncts that linearly follow the VP would result from a leftward movement of the VP. The same type of analysis imposes itself if all adjuncts are reanalyzed as specifiers of functional heads (cf. 'The Status of Adjunction' above).

(30) a. 
b. 
A generalized ban on right-adjunction will impact on a range of issues, such as, the structure of clauses with right dislocated material (31a), or the position of the extraposed clause (31b) (see the papers in Beerman *et al.*, 1997), or the question of how to handle relative clauses that follow the head noun (31c) (see Kayne, 1994).

(31) a. Elle ne l'a pas acheté, [$_{DP}$ ce livre].
she ne it has not bought, this book.
b. It did not surprise me at all [$_{CP}$ that she did not come back].
c. Nobody believed the claim [$_{CP}$ that John made].

Some Alternative Views

Projections and Features

Muysken (1981) attempted to simplify the X-bar format in terms of a relation between a head and a phrase. He assumed that a specific constituent may be associated with a combination of two binary features [± projection] and [± maximal]. The head of a projection (X in (5a)) corresponds to an entity with the features [− projection, − maximal]; the maximal projection will correspond to [+ projection, + maximal]. In the Minimalist approach, Chomsky (1995) capitalizes on Muysken's insights and elaborates bare phrase structure (Chomsky, 1995). One salient feature of this approach is that it dispenses with nonbranching projections.

Alternative Implementations

The discussion above presents the core components of X-bar theory in the generative tradition represented by the government binding/principles and parameters model. There exist different implementations of the theory where differences may affect a number of areas of the theory.

For instance, in generalized phrase structure grammar (GPSG), the bar notation was captured by means of a specific BAR feature in the feature structures labeling the nodes of a tree. The BAR feature could have the values 0, 1, 2. Thus, a head noun was a N with the bar value 0: [N+, V−, BAR:0], and its maximal projection, that is an NP, would be a N with the bar value 2: [N+, V−, BAR:2].

In head-driven phrase structure grammar (HPSG) (Pollard and Sag, 1994; Sag and Wasow, 1999), which developed from GPSG, the notation is simplified (*see also* **Head-Driven Phrase Structure Grammar**). The feature BAR as such no longer exists: the head of the structure has the feature HEAD. The distinction in projection levels is not maintained: the maximal projection of a head is the highest projection of the type phrase of that category in the structure that is associated with the relevant head. This approach is reminiscent of Muysken's (1986) reinterpretation of X-bar theory, and of recent proposals in terms of bare phrase structure (Chomsky, 1995).

There are additional differences between the frameworks. For instance, in HPSG the binary branching restriction is not generalized. Adjuncts are not necessarily distinguished from complements by their level of attachment (i.e., the bar level): for English, Bouma *et al.* (2001) propose that postverbal adjuncts are sisters to V, whereas preverbal adjuncts are adjoined to VP.

Xhosa

M W Visser, University of Stellenbosch, Stellenbosch, South Africa

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Xhosa (or isiXhosa, with the noun class prefix) belongs, with isiZulu (Zulu) and isiNdebele (Ndebele), to the Zunda subgroup of the Nguni group of the Southeastern Zone of Bantu languages. This zone also includes the Sotho, Venda, and Tsonga language groups. In terms of Guthrie's (1967–1971) classification, isiXhosa is identified as S41 (Doke, 1943, 1954; Piron, 1998; Gowlett, 2003; Nurse and Philippson, 2003). The Bantu family forms part of the larger Niger-Congo family of African languages of which the three other major families are Afroasiatic, Nilo-Saharan, and Khoisan (Greenberg, 1963; Heine and Nurse, 2000b; Williamson and Blench, 2000). Specific areas in the Eastern Cape province of South African have historically been associated with the various dialects or local forms of isiXhosa, namely isiGcaleka, isiNdlambe, isiGaika, isiThembu, isiBomvana, isiMpondomise, isiMpondo, and isiXesibe.

With the establishment of a democratic South Africa in 1994, isiXhosa has obtained the status of an official language, together with eight other Bantu languages spoken in South Africa, namely isiZulu, isiNdebele, Siswati (Swati), Sesotho (Southern Sotho), Sepedi/Sesotho sa Leboa (Northern Sotho), Setswana (Tswana), Tshivenda (Venda), and Xitsonga (Tonga). The government has introduced significant legislation through the Department of Arts and Culture for promoting the status and use of these official languages in government, education, and business, in addition to the predominant use of English. Huge challenges exist for accomplishing this goal, which includes urgent work in the fields of terminology development, language in education policy, and the teaching and learning of the indigenous African languages (Webb, 2001; Visser, 2004, 2005).

Nouns and Noun Phrases

Noun Classes

The morphology and semantics of the noun class system of isiXhosa is typical of the Bantu languages (Greenberg, 1963; Welmers, 1973; Du Plessis, 1978; Poulos and Msimang 1998; Piron 1998; Williamson and Blench, 2000; Gowlet, 2003). IsiXhosa has nouns in all noun classes from class 1 to 15, excluding class 12 and 13. The locative classes 16, 17, and 18 are morphologically fossilized; thus, they all exhibit the associated locative agreement subject- and object-verb agreement morpheme *ku-* rather than the distinct agreement morphemes of class 16, 17, and 18. As is general to the Bantu languages for the first 10 classes, the consecutive odd and even class numbers are regular singular-plural pairs. The noun class prefixes have a VCV syllable structure, except for classes 1, 3, and 9; the postnasal vowel in classes 1 and 3 has been deleted, and class 9 has the prefix *in-*. Classes 1a and 2a, subclasses of classes 1 and 2, respectively, have only vowel prefixes. Table 1 shows the noun class prefixes of isiXhosa.

Nominal Suffixes

Nouns in isiXhosa can regularly take suffixes that denote the property of feminine *–azi-*, augmentative *-azi,* and reciprocal *-ana*, as shown in Table 2.

Agreement Morphology with Nominal Modifiers

As is characteristic of the Bantu languages, isiXhosa exhibits agreement morphology of the nominal modifiers with the head noun, where the latter may be a lexical noun or a phonetically empty pronominal (Doke, 1954; Greenberg, 1963; Guthrie, 1967–1971; Welmers, 1973; Du Plessis and Visser, 1992; Gowlet 2003; Nurse and Philippson, 2003b). The nominal modifiers identified for isiXhosa include demonstratives, adjectives, nominal relatives, clausal relatives, numerals, quantifiers, possessives, and enumeratives (Louw, 1963; Du Plessis, 1978, 1983; Visser, 1984, 2002; Du Plessis and Visser, 1992). The examples that follow illustrate the agreement morphology of the adjective and possessive with pairs of lexical head nouns in classes 1, 2, 5, 6, 7, and 8.

Table 1 Noun class prefixes of IsiXhosa

Noun class	*Prefix*	*Example noun*
1	um-	umfazi 'woman'
2	aba-	abafazi 'women'
1a	u-	utata 'father'
2a	oo-	ootala 'fathers/father and company'
3	um-	umlilo 'fire'
4	imi-	imililo 'fires'
5	i(li)-	ilitye 'stone'
6	ama-	amatye 'stones'
7	isi-	isiqhamo 'fruit'
8	izi-	iziqhamo 'fruits'
9	i(n)-	indlu 'house'
10	i(z)i(n)-	izindlu 'houses'
11	ulu-	uluthi 'stick'
14	ubu-	ubusika 'winter'
15	uku-	ukutya 'food'

Table 2 Nominal suffixes: feminine, augmentative, and diminutive

-kazi FEM	inkosi 'chief';	inkosikazi 'chieftainess'
	ixhego 'old man';	ixhegokazi 'old woman'
	utitshala 'teacher';	utitshalakazi 'female teacher'
-kazi AUG	umthi 'tree';	umthikazi 'big tree'
	intaba 'mountain';	intabakazi 'big mountain'
	indlu 'house'	indlukazi 'big house'
–ana DIM	indoda 'man';	indodana 'small man'
	incwadi 'book';	incwadana 'small book'
	ilitye 'stone';	ilityana 'small stone'

Source: Du Plessis (1978, 1997); Louw (1963).

- The head noun is in class 1.

(1a) umntwana wam omhle
umntwana u-a-m om-hle
child AGR-GEN-mine AGR-beautiful
'my beautiful child'

- The head noun is in class 2.

(1b) abantwana bam abahle
abantwana ba-a-m aba-hle
children AGR-GEN-mine AGR-hle
'my beautiful children'

- The head noun is in class 5.

(1c) ihashe lam elihle
ihashe li-a-m eli-hle
horse AGR-GEN-mine AGR-beautiful
'my beautiful horse'

- The head noun is in class 6.

(1d) amahashe am amahle
amahashe a-a-m ama-hle
horses AGR-GEN-mine AGR-beautiful
'my beautiful horses'

- The head noun is in class 7.

(1e) isitya sam esihle
isitya si-a-m esi-hle
dish AGR-GEN-m AGR-hle
'my beautiful dish'

- The head noun is in class 8.

(1f) izitya zam ezihle
izitya zi-a-m ezi-hle
dishes AGR-GEN-mine AGR-beautiful
'my beautiful dishes'

Derived Nouns IsiXhosa exhibits regular nominal derivation from verbs and, to a less regular degree, from other word categories such as adjectives and nominal relatives (Louw, 1963; Du Plessis, 1978). The examples in Table 3 illustrate deverbal nouns in a range of noun classes.

Table 3 Deverbal nouns

Verb	*Deverbal noun*	
	Human	*Nonhuman*
-thenga 'buy'	umthengi 'buyer' (class 1)	intengo 'buy' (class 9)
-funda 'read, learn'	umfundi 'learner, student' (class 1)	imfundo 'education' (class 9)
-dlala 'play'	umdlali 'player' (class 1)	umdlalo 'game' (class 3)
-hamba 'travel', 'gula 'be ill'	umhambi 'traveller' (class 1)	uhambo 'travel' (class 11)
	isigulana 'patient' (class 7)	ingulo 'illness' (class 9)
-thanda 'like, love'	isithandwa 'beloved' (class 7)	uthando 'love' (class 11)

Compound Nouns

Compound nouns are common in isiXhosa, and this is especially salient in proper nouns.

(2a) umninikhaya < umnini-ikhaya
'home owner' owner-home
(2b) impilontle < impilo-entle
'good health' life-AGR-good
(2c) indlalifa < indla-ilifa
'person who inherits' eater-inheritance
(2d) imalimboleko < imali-imboleko
'loan' money-loan
(2e) uNtombizobawo < u-ntombi-za-ubawo
'girls of father' AGR(cl.1)-girls-of-father'
(2f) uNoxolo < u-No-uxolo
'the one with peace' AGR(cl.1)-Fem-peace
(2g) uMzimkhulu < u-Mzi-M-khulu
'big house' AGR(cl.1)-house-AGR-big
(2h) uNtombi zandile < u-Ntombi-zi-and-ile
'the girls have increased' AGR(cl.1)-girls-AGR(cl.10)-increase-Perf.

Verbs, Verb Phrases, and Clauses

Transitivity and Verbal Derivation

IsiXhosa has a wide range of nonderived verbs, which are intransitive and monotransitive. A smaller number of nonderived verbs are ditransitive, as shown in the following examples. Intransitive verbs (3) include experiencer verbs, motion verbs, and weather verbs.

(3a) -gula 'be ill'
(3b) -vuya 'be happy'
(3c) -sebenza 'work'
(3d) -hamba 'travel'
(3e) -phuma 'go out, exit'
(3f) -tshona 'sink'
(3g) -jika 'turn'
(3h) -buya 'return'

Verbs from a wide range of semantic classes appear as nonderived monotransitive verbs, as illustrated by the following examples.

- Verbs of change.

(4a) -aphula 'break'
(4b) -goba 'bend'
(4c) -pheka 'cook'
(4d) -oja 'roast'
(4e) -vala 'close'

- Verbs of change of possession.

(5a) -qokelela 'collect'
(5a) -fumana 'get, obtain'
(5a) -(i)ba 'steal'
(5a) -kha 'pick (fruit)'

- Verbs of communication.

(6a) -bika 'report'
(6b) -thetha 'speak'
(6c) -ncokola 'converse'
(6d) -hleba 'gossip'
(6e) -geza 'joke'

- Verbs of contact.

(7a) -beka 'put'
(7b) -tyala 'plant'
(7c) -xhoma 'hang'
(7d) -sula 'wipe'
(7e) -khupha 'take out'
(7f) -galela 'pour'

- Verbs of creation.

(8a) -qingqa 'carve'
(8b) -xovula 'knead'
(8c) -zoba 'draw'
(8d) -akha 'build'
(8e) -bhaka 'bake'

- Verbs of perception.

(9a) -bona 'see'
(9b) -(i)va 'hear/feel/taste'
(9c) -ngcamla 'taste'
(9d) -ngqina 'witness'
(9e) -jonga 'look at'

- Verbs of social interaction.

(10a) -vuma 'agree'
(10a) -qhula 'joke'
(10a) -tyelela 'visit'

Examples of nonderived ditransitive verbs appear in (11).

(11a) -nika 'give'
(11b) -pha 'give (as gift)'
(11c) -boleka 'lend'
(11d) -vimba 'refuse'
(11e) -buza 'ask'
(11f) -cela 'request'

Table 4 Reduplicated applicative forms

Verb	*Reduplicated applicative*
-bopha 'tie'	-bophelela 'tie thoroughly'
-funa 'search'	-funelela 'search thoroughly'
-sula 'wipe'	-sulelela 'wipe thoroughly'

As is typical of the Bantu languages, the transitivity properties of verbs in isiXhosa can be altered by suffixation of various verbal derivational suffixes, which can appear in combination with one another (Satyo, 1986) and which can be reduplicated to achieve various semantic effects. The applicative (APPLIC) and causative suffixes are transitivizing suffixes in that they introduce a new NP argument to the verb (Du Plessis, 1978, 1980b, 1997; Du Plessis and Visser 1992, 1998). When these suffixes appear, intransitive verbs becomes monotransitive and monotransitive verb become ditransitive. The applicative suffix can introduce an NP argument bearing the semantic role of benefactive, malefactive, recipient, purpose, and cause/reason, as shown in the examples in (12) (AGRS stands for subject agreement).

(12a) umfazi ufundela
umfazi u-fund-el-a
woman AGRS-read-APPLIC-PRES
abantwana amabali
abantwana amabali
children stories
'the woman reads stories for the children'

(12b) inkwenkwe ibalekela indebe
inkwenkwe i-balek-el-a indebe
boy AGRS-run-APPLIC-PRES cup
'the boy is running for the cup'

(12c) umfazi ulilela ilahleko
umfazi u-lil-el-a ilahleko
woman AGRS-cry-APPLIC-PRES loss
'the woman cries for (her) loss'

(12d) abafazi baphekela
abafazi ba-pheke-el-a
women AGRS-cook-APPLIC-PRES
umtshato inyama
umtshato inyama
wedding meat
'The women cooks meat for the wedding'

The applicative can appear in a reduplicated form to denote an intensified action, as shown in Table 4.

Causative Suffix

The causative (CAUS) suffix *-is-* regularly denotes three kinds of meanings, depending on the verbal semantics and the pragmatic context: coercive ('make/force to

do something'), assistive ('help do something'), and permissive ('let do something').

(13a) umfana ulimisa utata intsimi
umfana u-lim-is-a utata intsimi
young.man AGRS-plough-CAUS-PRES father field
'the young man helps his father plough the field'

(13b) utitshala ubhalisa abantwana ileta
utitshala u-bhal-is-a abantwana ileta
teacher AGRS-write-CAUS-PRES children letter
'the teacher makes/helps/lets write the children a letter'

Detransitivising Verbal Affixes

The reciprocal (RECIP) suffix *-ana* (14) and the reflexive (REFL) verbal prefix *-zi-* (15) in isiXhosa are detransitivizing morphemes, as is typical of the Bantu languages.

(14a) abantu bayathandana
abantu ba-ya-thand-an-a
people AGRS-PRES-like-RECIP-PRES
'the people like each other'

(14b) uZola noNomsa bayathandana
uZola na-uNomsa AGRS-PRES-thand-an-a
Zola and-Nomsa like-RECIP-PRES
'Zula and Nomsa like/love each other'

(14c) uZola uthandana noNomsa
uZola u-thand-an-a na-uNomsa
Zola AGRS-like-RECIP-PRES with-Nomsa
'Zola and Nomsa like/love each other'

(15a) umntwana uyazibona
umntwana u-ya-zi-bon-a
child AGRS-PRES-REFL-see-PRES
'the child sees himself/herself'

(15b) abantwana bayazihlamba
abantwana ba-ya-zi-hlamb-a
children AGRS-PRES-REFL-wash-PRES
'the children were themselves'

Unaccusative Verbal Suffixes: Passive and Neuter-Passive

Passive (PASS) *-w-* (16) and neuter-passive (NEUT. PASS) stative *-ele-/-akal-* (17) verbal suffixes are unaccusative, in that the object of a transitive verb must either raise to become the subject of the verb or remain in the object position and receive nominative case from a phonetically empty existential subject pronominal associated with the subject agreement prefix *ku-* on the verb (Visser, 1986; Du Plessis and Visser, 1992b, 1998).

(16a) incwadi iyafunwa ngumfundi
incwadi i-ya-fun-w-a ng-umfundi
book AGRS-PRES-want-PASS-pres cop-student
'the book is wanted/searched for by the student'

(16b) kufunwa incwadi ngumfundi
ku-fun-wa incwadi ng-umfundi
EXIST.AGRS-want/search-PASS.PRES book cop-student
'there is being wanted a book by the student'

(17a) incwadi iyafuneka kumfundi
incwadi i-ya-fun-ek-a ku-umfundi
book AGRS-PRES-want-NEUT.PASS-PRES to-student
'a book is needed to (for) the student'

(17b) kufuneka incwadi kumfundi
ku-fun-ek-a incwadi ku-umfundi
EXIST.AGRS-want-NEUT.PASS-PRES book to-student
'there is a book is needed to (for) the student'

(17c) intaba iyabonakala
intaba i-ya-bon-akal-a
mountain AGRS-PRES-see-NEUT.PASS-PRES
'the mountain is visible'

(17d) kubonakala intaba
ku-bon-akal-a intaba
EXIST.AGRS-see-NEUT.PASS-PRES mountain
'the mountain is visible'

The neuter-passive suffix *-ek-/-akal-* changes the verb into a stative verb, as shown in Table 5.

Verbal Inflection

IsiXhosa exhibits the inflectional morphemes typical of the Bantu languages, namely agreement, tense, aspect, mood, and negative (Du Plessis, 1986, 1997; Du Plessis and Visser, 1992b, 1998; Gowlett, 2003).

Subject and Object Agreement Prefixes The isiXhosa verb, like verbs in the Bantu languages in general, exhibits a subject agreement prefix (AGRS), which appears obligatorily, except with imperative mood verbs and certain instances of deficient verbs. The isiXhosa verb also contains an object agreement prefix (AGRO), which in general appears optionally (Du Plessis, 1978, 1997) and is often used to emphasize the verb phrase or to establish the object feature when the object argument is separated from the verb

Table 5 Intransitive-transitive verbal pairs with the consonant *-k-* and *-l-*

Intransitive stative	*Transitive*
-guquka 'be turned'	-guqula 'turn'
-aphuka 'be broken'	-aphula 'break'
-ahluka 'be separated/parted'	-ahlula 'separate'
-phekula 'be turned upside'	-phekula 'turn upside'
-khawuka 'be broken off'	-khawula 'break off'
-sombuluka 'be unfolded'	-sombulula 'unfold'

Source: Du Plessis and Visser (1998).

by intervening lexical or phrasal categories. In the examples in (18), the noun classes of the NP subject and object appear in brackets.

(18a) umntwana uyayifunda incwadi
umntwana u-ya-yi-fund-a incwadi
[class 1] [class 9]
child AGRS-PRES-AGRO-read-PRES book
'the child reads a book'

(18b) abantwana bayazifunda iincwadi
abantwana ba-ya-zi-funda iincwadi
[class 2] [class 10]
children AGRS-PRES-AGRO-read.PRES books
'the children read the books'

(18c) amadoda ayabusela utywala
amadoda a-ya-bu-sela utywala
[class 6] [class 14]
men AGRS-PRES-AGRO-drink beer
'the men drink beer'

Sentences like these, in which the object co-occurs with an object agreement prefix, denote additional emphasis on the verb phrase.

Aspect Morphemes The verbal inflectional morphology in isiXhosa contain a number of prefixes that denote aspectual features. These prefixes include *-sa-* 'still' (the progressive, PROG), *-ka-* 'not, get', and *-yawa-* 'as usual'. The potential morpheme *-nga-* denotes 'ability', 'possibility', or 'permission' (Louw, 1963; Du Plessis, 1978, 1997).

(19a) abafundi basafunda
abafundi ba-sa-fund-a
students AGRS-PROG-learn/read-PRES
'the students are still reading/learning'

(19b) abafundi abakafundi
abafundi a-ba-ka-fund-i
students NEG-AGRS-not-read-NEG
'the students have not read yet'

(19c) abafundi bayawafunda
abafundi ba-yawa-fund-a
students AGRS-as.usual-read-PRES
'the students are studying as usual'

(19d) abafundi bangaphumelela
abafundi ba-nga-phumelela
student AGRS-can/may-succeed
'the students can/may succeed'

Tense Inflection IsiXhosa has the typical tense distinctions found in the Bantu languages: present tense, perfect past tense, remote (A-) past tense, future tense, and compound (recent and remote) past tenses. The compound tenses appear as complex sentence constructions with a deficient verb taking a participial clause complement. The various past tenses are associated with specific features of (im)perfectivity (Louw, 1963; Du Plessis, 1978, 1986, 1997; Poulos and Msimang, 1998).

Present Tense The present tense verb form in isiXhosa can exhibit features of habituality and emphasis, in addition to denoting a literal present tense activity (Du Plessis, 1986, 1997).

(20a) iintombi ziphendula imibuzo
iintombi zi-phendul-a imibuzo
girls AGRS-answer-PRES questions
'the girls answer the questions'

(20b) iintombi aziphenduli mibuzo
iintombi a-zi-phendul-i mibuzo
girls NEG-AGRS-answer-NEG questions
'the girls do not answer (any) questions'

(20c) iintombi aziyiphenduli imibuzo
iintombi a-zi-yi-phendul-i imibuzo
girls NEG-AGRS-AGRO-answer-NEG questions
'the girls do not answer the (specific) questions'

The negative sentences in (20b) and (20c) illustrate the indefinite and definite negative, respectively. The former is characterized by the absence of the initial vowel (the preprefix) of the object NP and the related absence of the object agreement prefix in the verb morphology, whereas the latter is characterized by the presence of the preprefix of the NP object argument and the associated presence of the object agreement prefix in the verb morphology (Visser, 2002). Similar definite and indefinite negatives may appear in all the other tenses.

Future Tense The future tense is characterized by the verb *-za* 'come' or *-ya* 'go' followed by the infinitive prefix on the main verb.

(21a) iintombi ziza/ziya
iintombi zi-za/zi-ya
girls AGRS-come/AGRS-go
kuphendula imibuzo
ku-phendula imibuzo
INF-answer questions
'the girls will answer the questions'

The use of the deficient verb *-za* in the future tense denotes an immediate future, whereas the use of the deficient verb *-ya* denotes either a remote future or an immediate future action with a high degree of certainty.

(21b) iintombi azizi/aziyi
iintombi a-zi-z-i/a-zi-y-i
girls NEG-AGRS-come-NEG/NEG-AGRS-go-NEG
kuphendula mibuzo
ku-phendula mibuzo
INF-answer questions
'the girls will answer the questions'

Perfect Past Tense The perfect past tense denotes an action in the recent past that has been completed (Louw, 1963; Du Plessis, 1978, 1997).

(22a) abafana basebenzile
abafana ba-sebenz-ile
young.men AGRS-work-PERF
'the young men worked'

(22b) abafana abasebenzanga
abafana a-ba-sebenz-anga
young.men NEG-AGRS-work-PERF.NEG
'the young men did not work'

Remote Past Tense The remote past tense verb takes a subject agreement prefix with a long rising-falling vowel *-a-*.

(23a) iintombi zacula iingoma
iintombi zi-a-cula iingoma
girls AGRS-PAST-sing songs
'the girls sang songs'

(23b) umfundi wabhala ileta
umfundi u-a-bhala ileta
student AGRS-PAST-write letter
'the student wrote a letter'

Compound Past Tenses The compound past tenses denote an activity or state that took place in the past but that has not been completed; hence, they exhibit the imperfective aspect. The lexical verb in these tenses are in the participial mood.

Recent Compound Past Tense The recent compound past tense is characterized by a perfect tense deficient verb *-be* taking a participial complement clause, as shown in the following examples.

(24a) iintombi zibe zicula iingoma
iintombi zi-b-e zi-cula iingoma
girls AGRS-be-PERF AGRS-sing songs
'the girls were singing songs'

(24b) iintombi zibe zingaculi ngoma
iintombi zi-b-e zi-nga-cul-i ngoma
girls AGRS-be-PERF AGRS-NEG-sing-NEG songs
'the girls were not singing (any) songs'

Remote Compound Past Tense The deficient verb *-ba/-ye* appears in the remote compound past tense taking the morpheme *-a-* in its subject agreement affix and subcategorizing for a participial complement clause, as shown in the following examples.

(25a) iintombi zaba zicula iingoma
iintombi zi-a-ba zi-cula iingoma
girls AGRS-PAST-be AGRS-sing songs
'the girls were singing songs'

(25b) iintombi zaba zingaculi ngoma
iintombi zi-a-ba zi-nga-cul-i ngoma
girls AGRS-PAST-be AGRS-NEG-sing-NEG songs
'the girls did not sing (any) songs'

Negative Inflection The negative inflection of isiXhosa is realized through verbal prefixation, infixation, and suffixation, depending on the mood properties of the verb (Du Plessis, 1978, 1997). The examples of negative sentences given in the previous section demonstrate that negation in indicative mood verbs is realized by a verbal prefix that occurs before the subject agreement prefix and by a verbal suffix, whereas in participial clauses (in the compound tenses) the negative morpheme (*-nga-*) appears after the subject agreement prefix together with a negative verbal suffix. Further examples of negative sentences in isiXhosa appear in the subsection on mood inflection next.

Mood Inflection Linguists differ on the number of moods that can be distinguished for isiXhosa and closely related languages such as isiZulu (Louw, 1963; Du Plessis, 1978, 1997; Poulos and Msimang, 1998). The following nine moods have been distinguished for isiXhosa.

Indicative Mood The indicative mood is used in main clauses for statements and questions. Indicative mood clauses may also appear as a complement clauses of factive verbs.

(26a) abafundi bahala uviwo
abafundi ba-bhal-a uviwo
student AGRS-write-PRES examination
'the student is writing examination'

(26b) abafundi ababhali viwo
abafundi a-ba-bhal-i viwo
students NEG-AGRS-write-NEG examination
'the students are not writing (any) examination'

(26c) abafundi abalubhali uviwo
abafundi a-ba-lu-bhal-i uviwo
students NEG-AGRS-AGRO-write-NEG examination
'the students are not writing the (specific) examination'

The sentences in (26) can be changed into questions by using rising intonation toward the sentence-final position.

The sentences in (26b) and (26c) illustrate the indefinite and definite negatives, respectively. The indefinite negative is characterized by the loss of the initial vowel of the noun class prefix of the object noun and the absence of the object agreement affix in the verbal morphology. The definite negative is characterized by the presence of the initial vowel of the object noun and the associated object agreement prefix in the verbal morphology. The indefinite-definite negative distinction also has an influence on the morphological form of several categories that function as nominal modifiers.

The indicative mood exhibits the tense distinctions discussed in the previous subsection on tense inflection.

Participial (Situative) Mood The participial mood is used in subordinate clauses that denote an activity or state that takes place simultaneously with the activity or state expressed by the main clause. It is clearly identifiable by its subject agreement morphology for noun classes 1, 2, and 6 and by morphemes that occur with monosyllabic and vowel verb stems in positive sentences. In addition, the participial mood regularly occurs after certain temporal conjunctives (as in 27c) and deficient verbs (as in 27d) (Louw, 1963; Du Plessis, 1978, 1997; Du Plessis and Visser, 1992b).

(27a) abafundi bathula
abafundi ba-thula
students AGRS-be.quiet
bebhala uviwo
be-bhala uviwo
AGR(PART)-write examination
'the students are quiet while they are writing examination'

(27b) abafundi babhala uviwo
abafundi ba-bhala uviwo
students AGRS-write examination
besiva imiyalelo
be-si-v-a imiyalelo
AGRS(PART)-AFF(PART)-hear-PRES instructions
'the students write examinations while hearing the instructions'

(27c) abafundi bathula xa
abafundi ba-thula xa
students AGRS-be.quiet when
bebhala uviwo
be-bhal-a uviwo
AGRS(PART)-write-PRES examination
'the students are quiet when they write examinations'

(27d) abafundi basoloko
abafundi ba-soloko
students AGRS-always.do
bebhala uviwo
be-bhal-a uviwo
AGRS(PART)-write-PRES examination
'the students always write examination'

(27e) abafundi babhala uviwo
abafundi ba-bhal-a uviwo
students AGRS-write-PRES examination
bengafundanga kakuhle
be-nga-fund-anga kakuhle
AGRS(PART)-NEG-learn-NEG well
'the students write examinations (while) they have not studied well'

The participial mood in isiXhosa can exhibit all the various tense forms discussed in the subsection on tense inflection.

Relative Mood The relative mood clause occurs widely as a nominal modifier in isiXhosa. It is characterized by the coalescence of a definitizing morpheme *-a-*, which also occurs with various other nominal modifiers, with the subject agreement prefix of the relative clause verb. This definitizing morpheme is, however, omitted when the relative clause head is the object argument of an indefinite negative verb or when the relative clause head occurs with a demonstrative pronoun. The relative clause in isiXhosa typically contains a resumptive pronoun, coreferential with the relative clause head, which can be realized as an object agreement prefix in the verbal morphology, a prepositional complement, or complement of a copulative, as illustrated by the following examples:

(28a) abafundi ababhala uviwo
abafundi a-ba-bhal-a uviwo
students AFF(DEF)-AGRS-write-PRES examination
bafunde kakuhle
ba-fund-e kakuhle
AGRS-learn-PERF well
'the students who write examinations have studied well'

(28b) aba bafundi babhala
aba bafundi ba-bhal-a
DEM students AGRS-write-PRES
uviwo bafunde kakuhle
uviwo ba-fund-e kakuhle
examinations AGRS-learn-PERF well
'these students who write examinations have studied well'

(28c) asibizi bafundi
a-si-biz-i bafundi
NEG-AGRS-call-NEG students
babhala uviwo
ba-bhal-a uviwo
AGRS-write-PRES examinations
'we do not call (any) students who write examinations'

(28d) abafundi enibafunayo
abafundi a-ni-ba-fun-a-yo
students AFF(DEF)-AGRS-AGRO-want-PRES-AFF(RC)
babhala uviwo
ba-bhal-a uviwo
AGRS-write-PRES examination
'the students who you want, are writing examination'

(28e) abafundi endiya kubo
abafundi a-ndi-y-a ku-bo
students AFF(RC)-I-go-PRES to-them
babhala uviwo
ba-bhal-a uviwo
AGRS-write-PRES examination
'the students to whom I am going write examinations'

(28f) utitshala ubiza abafundi
utitshala u-biz-a abafundi
teacher AGRS-call-PRES students
abangabhali viwo
a-ba-nga-bhal-i viwo
AFF(RC)-AGRS-NEG-write-NEG examination
'the teacher is calling the students who are not writing (any) examination'

The relative mood can appear in all the various tenses discussed in the subsection on tense inflection.

A relative mood clause can also occur after certain conjunctives (as in (29a)), often as an alternative to the participial mood clause due to the phenomenon that the distinction between the relative mood and participial mood is vacuous in some Southern Bantu languages such as Xitsonga.

(29a) abafundi bathula
abafundi ba-thul-a
students AGRS-be.quiet-PRES
xa bafundayo
xa ba-fund-a-yo
when AGRS-learn-PRES-AFF(RC)
'the students are quiet when they study'

(29b) kuseloko abafundi bafundayo
kuseloko abafundi ba-fund-a-yo
since students AGRS-learn-PRES-AFF(RC)
kakuhle baphumelela uviwo
kakuhle ba-phumelel-a uviwo
well AGRS-pass-PRES examination
'since the students study well they pass the examination'

Subjunctive Mood The subjunctive mood is associated with a range of semantic contexts. It can appear in clauses denoting successive actions, necessity and obligation, purpose, wish, and prohibition, as shown in the following examples, in which these meanings are often determined by the semantic features of the verb by which it is subcategorized.

The subjunctive mood is clearly identifiable by overt morphology, specifically the verbal suffix *-e* and the subject agreement prefix *a-* for class 1 nouns. Its morphology is invariable, and it does not exhibit tense distinctions.

- Successive actions.

(30) abantwana bavuka kusasa bahlambe
abantwana ba-vuk-e ba-hlamb-e
children AGRS-wake-up early
ubuso batye
ubuso ba-ty-e
AGRS-wash-AFF(SUBJ) AGRS-eat-AFF(SUBJ)
babulise abazali
ba bulis-e abazali
AGRS-greet-AFF(SUBJ) parents
baye esikolweni
ba-y-e isikolo-ini
AGRS-go-AFF(SUBJ) LOC school-LOC
'the children wake up early, wash (their) faces, eat, greet (their) parents, and go to school'

- Necessity, obligation.

(31a) utitshala uyalela ukuba
utitshala u-yalel-a ukuba
teacher AGRS-instruct-PRES COMP
abantwana bafunde iincwadi
abantwana ba-fund-e incwadi
children AGRS-read-AFF(SUBJ) book
'the teacher instructs the children to read a book'

(31b) kufuneka ukuba abafundi
ku-funeka ukuba abafundi
EXIST-be.needed COMP students
babhale uviwo
ba-bhal-e uviwo
AGRS-write-AFF(SUBJ) examination
'it is necessary that the students write the examination'

- Request, wish, desire.

(32a) utitshala ucela ukuba
utitshala u-cel-a ukuba
teacher AGRS-request-PRES COMP
abantwana bafunde incwadi
abantwana ba-fund-e incwadi
children AGRS-read-AFF(SUBJ) book
'the teacher requests the children to read a/the book'

(32b) abazali banqwenela ukuba
abazali ba-nqwenel-a ukuba
parents AGRS-wish-PRES COMP
abafundi baphumelele uviwo
abafundi ba-phumelel-e uviwo
students AGRS-pass-AFF(SUBJ) examination
'the parents wish that the students pass the examination'

- Purpose.

(33a) abafundi bafunda kakhulu ukuze
abafundi ba-fund-a kakhulu ukuze
students AGRS-learn-PRES much COMP
baphumelele uviwo
ba-phumelel-e uviwo
AGRS-pass-AFF(SUBJ) examination
'the students study hard so that they pass the examination'

(33b) abafundi bafundela ukuba
abafundi ba-fund-el-a ukuba
students AGRS-learn-APPLIC-PRES COMP
baphumelele uviwo
ba-phumelel-e uviwo
AGRS-pass-AFF(SUBJ) examination
'the students study so that they pass the examination'

(33c) abafana basebenza evenkileni
abafana ba-sebenz-a e-ivenkile-ini
young.men AGRS-work-PRES LOC-shop-LOC
ukuze bafumane imali
ukuze ba-fuman-e imali
COMP AGRS-get-AFF(SUBJ) money
'the young men work in the shop so that they get money'

- Questions expressing potential necessity or obligation. Subjunctive mood interrogatives are allowed only with first-person subject pronominals.

(34a) ndincede aba bantu?
ndi-nced-e aba bantu
AGRS(1.SING)-help-AFF(SUBJ) DEM people
'must I help these people?'

(34b) singene endlwini?
si-ngen-e e-indlu-ini
AGRS(1.PL)-enter-AFF(SUBJ) LOC-house-LOC
'must we enter into the house?'

- Prohibition. A subjunctive mood clause that denotes a prohibition must have a subject pronominal in the second person and must be in the negative.

(35a) ungayibeki incwadi apha!
u-nga-yi-bek-i incwadi apha
AGRS (2.SING)-NEG-AGRO-put-NEG book here
'don't put the book here!'

(35b) ningalibali ukuthenga isonka!
ni-nga-libal-i uku-thenga isonka
AGRS (2.PL)-neg-forget-NEG INF-buy bread
'don't forget to buy bread!'

- Exhortation.

(36a) usale kamnandi
u-sal-e kamnandi
AGRS(1.SING)-stay(behind)-AFF(SUBJ) nicely
'you stay (behind) nicely'

(36b) uhambe kakuhle
u-hamb-e kakuhle
AGRS(1.SING)-travel-AFF(SUBJ) well
'you stay (behind) well'

(36c) nilale kamnand
ini-lal-e kamnandi
AGRS(1.PL) nicely
'you must sleep nicely'

- The subjunctive mood in the complement clause of deficient verbs.

(37a) umfundi uphinda abhale uviwo
umfundi u-phinda a-bhal-e uviwo
student AGRS-do. again AGRS-write-AFF(SUBJ) examination
'the student again writes the examination'

(37b) umfundi ukhawuleza
umfundi u-khawuleza
student AGRS-do.quickly
abhale uviwo
a-bhal-e uviwo
AGRS-write-AFF(SUBJ) examination
'the student quickly writes the examination'

Consecutive Mood The consecutive (CONS) mood occurs in clauses that denote successive actions or states, in which the first verb is in the past tense. It is an invariable form that cannot have tense distinctions.

(38) umntwana uvuke wahlamba
umntwana u-vuk-e u-a-hlamba
child AGRS-wake-PERF AGRS-AFF(CONS)-wash
ubuso watya wabulisa
ubuso u-a-tya u-a-bulisa
face AGRS-AFF(CONS)-eat AGRS-AFF(CONS)-greet
abazali waya esikolweni
abazali u-a-ya e-isikolo-ini
parents AGRS-AFF(CONS)-go LOC-school-LOC
'the child woke up, washed (his/her) face, ate, greeted (his/her) parents, and went to school'

A consecutive mood clause may occur as complement of certain deficient verbs, in which the deficient verb itself is normally in the past tense.

(39a) umfundi uphinde wabhala uviwo
umfundi u-phind-e wa-bhala uviwo
student AGRS-do. again-PERF AGRS (CONS)-write examination
'the student again wrote the examination'

(39b) umfundi ukhawuleze wabhala uviwo
umfundi u-khawulez-e wa-bhala uviwo
student AGRS-do. quickly-PERF AGRS (CONS)-write examination
'the student quickly wrote the examination'

Imperative Mood The imperative is used for commands and instructions. If the command or instruction is directed to more than one person, the verb takes the suffix *-ni*.

(40a) funda incwadi!
read book
'you (SING) read the book!'
(40b) fundani incwadi!
funda-ni incwadi
read-PL book
'you (PL) read the book!'

Hortative Mood The hortative (HORT) mood is used in clauses that express polite direct requests, in which instance the deficient verb *-kha* is used. The hortative can also be used to express indirect requests or instructions.

(41a) khawuphendule imibuzo
kha-wu-phendul-e imibuzo
let-AGRS(1.SING)-answer-AFF(HORT) questions
'please answer the questions'
(41b) khanifunde iincwadi
kha-ni-fund-e iincwadi
let-AGRS(1.PL)-read-AFF(HORT) books
'please read the books'
(41c) abafundi mabaphendule imibuzo
abafundi ma-ba-phendul-e imibuzo
students AFF(HORT)-AGRS-answer-AFF(HORT) questions
'the students must answer the questions'
(41d) umntwana makafunde iincwadi
umntwana ma-ka-fund-e iincwadi
child AFF(HORT)-AGRS-read-AFF(HORT) books
'the child must read the book'
(41e) abafundi mabangayiphenduli imibuzo
abafundi ma-ba-nga-yi-phendul-i imibuzo
students AFF(HORT)-AGRS-NEG-AGRO-answer-AFF(HORT) questions
'the students must not answer the questions'

The hortative does not exemplify any tense distinctions.

Temporal Mood The temporal (TEMP) mood occurs as a subordinate clause that denotes an activity that takes place (partly) simultaneously with the activity or state denoted by the main clause. It contains the invariable verbal prefix *-aku*. The logical subject argument usually appears in the postverbal position.

(42a) bakufunda abafundi
ba-aku-funda abafundi
AGRS-AFF(TEMP)-study students
baxoxa incwadi
ba-xox-a iincwadi
AGRS-discuss-PRES books
'when the students study, they discuss the books'

(42b) sakufika ekhaya
si-aku-fika e-ikhaya
LOC-home AGRS-PRES-rest-PRES
siyaphumla
si-ya-phuml-a
AGRS-AFF(TEMP)-arrive
'when we arrive at home, we rest'

(42c) bakungasebenzi abafundi badiniwe
ba-aku-nga-sebenz-i abafundi ba-diniwe
AGRS-AFF(TEMP)-NEG-work-NEG students AGRS-tired
'when the students do not work, they are tired'

Infinitive Mood The infinitive mood clause is regularly subcategorized by specific (cognition) verbs, as in (43a) and (43b). It may occur in NP argument positions in a nominalized grammatical function, as in (43c) and (43d). Some verbs can allow a purposive infinitival complement only if they have an applicative suffix, as in (43e) and (43f) below (Visser, 1989).

(43a) abafana bayakwazi ukunceda abazali
abafana ba-ya-ku-azi uku-nceda abazali
young.men AGRS-PRES-AGRO-know INF-help parents
'the young men know (how) to help (their) parents'

(43b) umfundi uyaqonda ukuphendula imibuzo
umfundi u-ya-qonda uku-phendula imibuzo
student AGRS-PRES-understand INF-answer questions
'the student understands to answer questions'

(43c) ukubhala kwabafundi kulungile
uku-bhala kwa-abafundi ku-lungile
INF-write GEN-students AGRS(EXIST)-good
'the writing of the students is good'

(43d) ukungafundi kwabafundi
uku-nga-fund-i kwa-abafundi
INF-NEG-learn-NEG GEN-students
kuyamangalisa
ku-ya-mangalisa
AGRS(EXIST)-PRES-amaze
'the nonlearning of the students amazes (people)'

(43e) abafana basebenzela ukufumana imali
abafana ba-sebenz-el-a uku-fumana imali
young.men AGRS-work-APPLIC-PRES INF-get money
'the young men work to get money'

(43f) abafundi bafundela ukuphumelela uvio
abafundi ba-fund-el-a uku-phumelela uvio
students AGRS-learn-APPLIC-PRES INF-pass examination
'the students study to pass the examination'

Ideophones IsiXhosa is characteristic of the Bantu languages in that it is rich in ideophones. Ideophones can function as predicates, adverbs, or interjections and are often onomatopoeic. They denote the manner or sound of an activity or the color of an object. The ideophone (IDEO) that forms part of a predicate has inherent lexical properties of transitivity. In isiXhosa, the verb *-thi,* which co-occurs with the ideophone to form a predicate, serves as the host element for inflection, but it can be omitted in certain instances (Du Plessis, 1978, Du Plessis and Visser, 1998).

Intransitive Ideophones

(44a) lo mntwana uhleli uthe
lo mntwana u-hleli u-th-e
DEM child AGRS-sit AGRS-do-PERF
qwa
qwa
ideo (upright)
'this child sat upright'

(44b) abantu bathi nqa
abantu ba-th-i nqa
people AGRS-do-PRES ideo (surprise)
ngale nto
nga-le nto
about-this thing
'the people are surprised by this thing'

(44c) ixhego lithe chu
ixhego li-th-e chu
old.man AGRS-do-PERF ideo (go.slowly)
waya endlini
wa-ya e-indlu-ini
AGRS(CONS)-go LOC-house-LOC
'the old man walked slowly and went to the house'

(44d) abafazi bathe xha
abafazi ba-th-e xha
women AGRS-do-PERF ideo (wait)
'the woman waited'

(44e) le ndoda ithe xhwenene
le ndoda i-th-e xhwenene
this man AGRS-do-PERF ideo (suddenly.stop)
'this man stopped suddenly'

The ideophones in (44a)–(44e) also illustrate the various click sounds, the ingressive sounds borrowed by isiXhosa from the Khoisan languages. The consonant *q* represents the palatal ingressive click sound [•], the consonant *c* represents the dental ingressive click sound [•], and the consonant *x* or (*xh*) represents the alveolateral ingressive click sound [•].

Transitive Ideophones

(45a) lo mfana wathi
lo mfana wa-th-i
DEM young.man AGRS-do-PRES
rhuthu intonga yakhe
rhuth intonga ya-khe
ideo (take.out) stick GEN-his
'this young man took out his stick'

(45b) lo mfana uthe
lo mfana u-th-e
DEM young.man AGRS-do-PERF
qhiwu indebe
qhiwu indebe
ideo (hold.high) cup
'this man held the cup high up'

(45c) bamthe hlasi ngengalo
ba-m-the-e hlasi nga-ingalo
AGRS-AGRO-do-PERF ideo (grab) by-arm
'they grabbed him on the arm'

(45d) bamthe nqaku lo mfana
ba-m-th-e nqaku lo mfana
AGRS-AGRO-do-PERF ideo (grab) DEM young.man
'they grabbed this young man'

Xu, Shen (d. 120? A.D.)

Y Gu, The Chinese Academy of Social Sciences, Beijing, China

© 2006 Elsevier Ltd. All rights reserved.

Shen Xu is almost exclusively known as the earliest lexicographer whose dictionary, *Shuowen Jiezi* (说文解字), has exerted lasting influence on Chinese dictionary making as well as on Chinese linguistics in general. Bibliographic information on him is almost non-existent.

The compilation of *Shuowen Jiezi* was completed in year 100 of the Later Han (25–220 A.D.). It was presented by the lexicographer's son to the Royal Court in 121. The title of the dictionary, *Shuowen Jiezi*, literally means expounding, *wen* (文), and anatomizing, *zi* (字). The two characters 文字 in modern Chinese have become one word meaning 'writing script.' In Xu's usage, however, the two were two words with different designations. *Wen* refers to a character that is both ideographic and semantic, whereas *zi* is a compound character that is both indicative and phonological. This clearly shows that the dictionary is concerned with character formations, apart from definitions of meanings. Historically, Xu's treatment of character formations was extremely significant and timely. The First Emperor, Qin Shihuang, pursued an orthographic reform, as a result

Xu, Shen (d. 120? A.D.)

Y Gu, The Chinese Academy of Social Sciences, Beijing, China

© 2006 Elsevier Ltd. All rights reserved.

Shen Xu is almost exclusively known as the earliest lexicographer whose dictionary, *Shuowen Jiezi* (说文解字), has exerted lasting influence on Chinese dictionary making as well as on Chinese linguistics in general. Bibliographic information on him is almost non-existent.

The compilation of *Shuowen Jiezi* was completed in year 100 of the Later Han (25–220 A.D.). It was presented by the lexicographer's son to the Royal Court in 121. The title of the dictionary, *Shuowen Jiezi*, literally means expounding, *wen* (文), and anatomizing, *zi* (字). The two characters 文字 in modern Chinese have become one word meaning 'writing script.' In Xu's usage, however, the two were two words with different designations. *Wen* refers to a character that is both ideographic and semantic, whereas *zi* is a compound character that is both indicative and phonological. This clearly shows that the dictionary is concerned with character formations, apart from definitions of meanings. Historically, Xu's treatment of character formations was extremely significant and timely. The First Emperor, Qin Shihuang, pursued an orthographic reform, as a result

of which the *li* font style of writing became popular. By the time of the Former Han (206 B.C.–25 A.D.), the classic cannons were copied by using the *li* font style. The classic cannons thus produced were known as 'present-day classics.' Not until the Later Han did the classic cannons in the more ancient font style *zhuan shu* (篆书) become popular. The cannons in this ancient font were known as 'ancient style classics.' Those producing the 'present-day classics,' being quite ignorant of character formation principles adopted by ancestors, introduced so many fresh errors into the classics that they were rendered totally unreliable. Xu's dictionary adopted the original ancient texts as its data base, and laid bare the ridiculous errors committed by his predecessors.

Shuowen Jiezi contains 9353 characters (in *zhuan* font style) and 1163 duplicates. The majority of characters found in ancient classics, including those created in the Han dynasty, are covered. The dictionary proved to be an undispensable tool for later generations to decipher ancient texts, oracle bone and bronze inscriptions in particular.

The characters are arranged according to the 'radicals,' i.e., component-forming characters. There are 514 headings, starting from *yi* (一) and terminating in *hai* (亥). In decomposing characters, Xu inherited the six formation principles, of course, with his own interpretations.

Shuowen Jiezi has been subject to textual studies and commentaries for many centuries, which has resulted in a rich pool of literature. The most influential ones are the following four: (1) *Shuowen Jiezi with Duan Yucai's commentary*, (2) Gui Fu's *Semantic study of Zhuowen Jiezi*, (3) Wang Yun's *Guided reading of Shuowen Jiezi*, and (4) Zhu Junsheng's *Phonological study of Shuowen Jiezi*.

Yakut

L Johanson, Mainz University, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Location and Speakers

Yakut (*saxa tïla*) belongs to the Northeastern or Siberian branch of Turkic languages. It has about 380 000 native speakers living in northeastern Siberia, mainly in the Yakut Autonomous Republic (*Saxa Avtonomnay Respublikata*) within the Russian Federation. The republic, whose capital is Yakutsk, has around one million inhabitants, of whom one-third are Yakuts.

The Yakut language occupies the easternmost and, together with Dolgan, the northernmost Turkic-speaking area. The huge Yakut territory has its center in the lowlands on the middle and lower reaches of Lena and its tributaries Aldan and Vilyuy; most Yakuts live in this region. In the northwest, the Yakut territory extends up to the Arctic Ocean, comprising the Khatanga river system. In the extreme northwest, speakers of Yakut live on the Taimyr peninsula, particularly on the southern slopes of the Byrranga mountain range. In the northeast, the territory extends to the lowlands of the Yana and Indigirka river systems, up to the New Siberian Islands, and even beyond the Kolyma river. Small groups of Yakut speakers live outside the republic, e.g., in the Magadan, Irkutsk, Chita, Amur, and Khabarovsk areas.

In spite of the strong dominance of Russian, which is the language of higher education, Yakut has a relatively strong status in the republic, also being used as a second language by many speakers of Evenki, Even, and Yukagir.

Origin and History

After their emigration to northeastern Siberia, the ancestors of the Yakuts lost their contact with other Turkic-speaking groups. Since their language has been geographically isolated from other Turkic varieties for many centuries, it exhibits features that sharply distinguish it from them and makes it unintelligible to speakers of other Turkic languages. Numerous archaic features show that the contact with the rest of the Turkic world was lost very early. On the other hand, a great number of deviations are the results of innovative developments.

The ancestors of the Yakuts seem to have belonged to the 'tree Kurikan tribes' (*üč qurïqan*) mentioned in the East Old Turkic stone inscriptions found in the Orkhon river valley. It is obvious that they lived for a relatively long time in the area surrounding Lake Baikal before they migrated northward. This is also indicated by the Yakut word *bayaγal* 'sea.' Various Turkic-speaking groups have settled in the Baikal region, also the ancestors of the Tuvans and old Uyghur groups. The Yakut language itself contains indications of an early habitat in the south, e.g., names of months that do not fit the climate of Yakutia and words for animals such as *tebien* 'camel.' Yakut oral traditions also tell us about a migration from the south to the north. Early Yakut tribes left their southern habitat, probably pushed by Buryat groups, and migrated northward along the Lena river. This exodus did not occur before the 13th century, since the memory of Chinggis and the Mongol campaigns is still alive in Yakut traditions.

The ancestors of the Yakuts had been subject to a certain Mongolian admixture prior to the migration. When proceeding northward along the Lena river, the Turkic-speaking immigrants mixed with and absorbed indigenous Evenkis, Evens, and Yukagirs. At the same time, they also pushed local Tungusic-speaking groups northwestward and northeastward. Yukagirs and Paleoasiatic groups were forced out to still more peripheral regions. For centuries, however, the Yakuts lived south of their present-day territory. It was only under the pressure of the Russian expansion in Siberia that they migrated to more arctic regions. Yakutia was incorporated in the Russian Empire in the 1620s.

While the Yakuts have preserved many features of the southern culture of cattle and horse breeders, they have also taken over elements of northern nomadism from their new neighbors, traditionally reindeer herders and hunter-gatherers. In spite of Christianization and Russification, their ethnic structure has remained relatively intact.

Related Languages and Language Contacts

Yakut is most closely related to its geographically nearest Turkic neighbors, Tuvan and Khakas of southern Siberia. The old Yakut self-designation *Ura:nxay* points to early connections with the territory of Tuva, which has also been referred to as Uryankhay. Some scholars have assumed that Yakut was originally a Kipchak Turkic language (*see* **Turkic Languages**).

Yakut has been in long and close contact with other languages. It shows strong traces of Mongolic influence. The period in which the ancestors of the Yakut settled on the shore of Lake Baikal led to close interaction with Buryat. An early impact on Yakut may also have been exerted by Yeniseian, a formerly widespread Paleoasiatic language. After the emigration to northern Siberia, the Turkic language of the Yakuts underwent strong substrate influence from Tungusic dialects. The next neighbors of Yakut are the North Tungusic languages Evenki and Even (Lamut), both of which appear to have Paleoasiatic substrates. The speakers of Evenki live in the northern and northwestern parts of Yakutia, whereas the Evens live in the northeastern parts, in particular in the basins of the rivers Indigirka, Yana, and Kolyma. The contacts with the isolated language Yukagir have also been important. The complex problems of language contact and language shift in the area are still unsolved.

The Written Language

No old Yakut literary documents are known. According to a tradition in Yakut folklore, however, the Yakuts once possessed written documents, which they lost on their way to the north. There is a rich Yakut oral literature comprising legends, epics, songs, etc. A modern literature began to develop at the beginning of the 20th century. A Cyrillic alphabet was created for Yakut by the German scholar Otto Böhtlingk in the mid-19th century. A new script, based on the International Phonetic Alphabet and designed by the Yakut linguist S. A. Novgorodov, was introduced in 1922. It was later replaced by a new Roman-based script, which was in use until a Cyrillic alphabet was introduced in 1939. The orthographic rules of the modern Yakut language have often been changed. They have, however, basically followed phonetic principles, mirroring the actual pronunciation with its numerous assimilations.

Distinctive Features

Yakut exhibits many linguistic features typical of the Turkic family (*see* **Turkic Languages**). It has, for example, a suffixing morphology, sound harmony, and a head-final constituent order. In the following, only a few distinctive features will be dealt with. In the notation of suffixes, capital letters indicate phonetic variation. Hyphens are used here to indicate morpheme boundaries.

Phonology

Yakut holds an exceptional position among the Turkic languages because of certain phonetic developments. Similar phenomena are sometimes found in contact languages such as Buryat and Evenki.

Like Turkmen and Khalaj in the southwestern part of the Turkic-speaking world, Yakut has preserved Proto-Turkic long vowels, e.g., *a:t* 'name' and *ü:t* 'milk.' Yakut has eight short vowels and eight long vowels including four diphthongs. The nonhigh long vowels are realized as diphthongs, e.g., *küöl* 'lake' < *kö:l*. Yakut *t* corresponds to the East Old Turkic intervocalic and word-final dental *δ*, e.g., atax 'leg,' *tot-* 'to become satiated.' Initial *s-* corresponds to *y-* in most other Turkic languages, e.g., *suol* 'way,' *sït-* 'to lie' (Turkish *yol, yat-*). The consonants *z, š*, and *č* have developed into *s* in Yakut, e.g., *seri*: 'army' < *čerig*. Initial *s-* has been deleted, e.g., *u:* 'water,' *ös* 'word'; cf. Turkish *su, söz*. Intervocalic *-s-*, however, has developed into *-h-*, e.g., *kuh-a* [duck-POSS.3.SG] 'his/her duck' (of *kus* 'duck'), *uhun* 'long'; cf. Turkish *kuş* 'bird,' *uzun* 'long.'

Yakut applies, like other Turkic languages, a front-back sound harmony, according to which native words contain either front or back sounds. The rounded-unrounded harmony is also well developed. The vowels *o* and *ö* may occur as suffix vowels, e.g., *kötör-ö* [bird-POSS.3.SG] 'his/her bird' (*kötör* 'bird').

Due to sound changes, progressive and regressive consonant assimilations, unstable vowels, etc., Yakut word forms often deviate from the typical Turkic agglutinative structure, e.g., *at* 'horse' vs. *ap-pït* [horse-POSS.1.PL] 'our horse,' *taγïs*-'to go out' vs. *taxs-ar* [go out-PRES.3.SG] 'goes out,' *kï:s* 'daughter' vs. *kï:h-ïm* [daughter-POSS.1.SG] 'my daughter.' Some pronouns have special oblique stems, e.g., *mi:gi-* vs. *min* 'I,' *man-* vs. *bu* 'this.' The third-person imperative form consists of the verbal stem, e.g., *as* 'open,' whereas the corresponding negative form exhibits a vowel element in front of the negation marker, e.g., *ah-ï-ma* [open-ï-NEG.IMP] 'don't open'; cf. Turkish *aç* [open.IMP], *açma* [open-NEG.IMP].

Grammar

Yakut displays some unique grammatical features, innovations partly due to Mongolic and/or Tungusic

influence. Striking features in the case system are the lack of a genitive and the fusion of dative and locative. The nominative is used instead of a genitive in constructions such as *kihi bïhaγ-a* [man knife-POSS] 'the man's knife.' The old locative-ablative has lost its spatial functions, assuming a partitive function with imperatives and necessitatives, e.g., *u:-ta aγal* [water-PART bring-IMP.2.SG] 'bring [some] water.' Its locative function has been taken over by the dative-locative in *-GA*, which expresses both location and goal, e.g., *guorak-ka* [town-DAT.LOC] 'in/to the town.' Special case suffixes occur with possessive markers. For instance, while *ak-ka* [horse-DAT.LOC] 'to the horse' is the dative-locative form of *at* 'horse,' *ap-p-ar* [horse-POSS.1.SG-DAT.LOC] 'to my horse' is the corresponding form of *at-ïm* 'my horse.' New cases have emerged in Yakut, an instrumental, a comparative, a comitative, and an adverbial case. An example of the latter is *kihi-li* [human being-ADV] 'in a human way' (*kihi* 'human being').

The Yakut yes-no question marker is *duo* or *du:*, whereas almost all other Turkic languages use markers of the type *mI*. An enclitic question particle *-iy* is added to interrogative pronouns and adverbs, e.g., *bu kimiy?* [this who-INTERROG] 'who is this?' Possession may be expressed by means of the adjective suffix *-la:x*, e.g., *Min ǰie-le:x-pin* [I house-PROVIDED.WITH-1P.SG.] 'I have a house.' The adjective *suox* 'nonexisting' (cf. Turkish *yok*) is used instead of the common Turkic privative suffix *-siz* 'without,' e.g., *u:-ta suox* [water-POSS nonexisting] 'without water'; cf. Turkish *su-suz* [water-PRIV]. Adjectives may be negated with a third-person possessive suffix plus *suox*, e.g., *kuhaγana suox* [bad-POSS.3.SG nonexisting] 'not bad'. The cardinals numbers from 11 to 19 are formed with *uon* 'ten' plus a digit, e.g., *uon tüört* [ten four] 'fourteen.' The tens from 40 to 90 are formed with a digit plus *uon* 'ten,' e.g., *tüört uon* [four ten] 'forty'; cf. Turkish *kirk*.

An archaic feature is the retention of the verbal suffix *-BIt*, which is otherwise only found in the southwestern branch of Turkic, e.g., *kel-bit* [come-PART] 'having come'; cf. Turkish *gel-miş* [come-PART]. As a finite form it has evidential (indirective) meaning, e.g., *kel-bit* [come-EV.PAST.3.SG] 'has evidently come'; cf. Turkish *gel-miş* [come-EV.PAST.3.SG] 'has evidently come.'

Lexicon

The basic lexicon of Yakut is of Turkic origin. Most words of foreign origin are Mongolic loans. There is an old Buryat layer from the early period of settlement on the shore of Lake Baikal. Even the pronoun *beye* 'self' has been copied from Mongolic. Loanwords from Tungusic often belong to the domain of husbandry and everyday life. A large portion of the Yakut lexicon is of unknown origin, probably due to contact with Paleoasiatic languages. The Russian impact on the lexicon has been considerable. Loanwords are in general assimilated to the Yakut word structure, e.g., *sïlaba:r* 'samovar,' *bïragra:mma* 'programme.'

Dialects

The differences between the Yakut dialects are comparatively small. There is a central group consisting of the Aldan, eastern and western Lena dialects, a northeastern group, influenced by Even, and a northwestern group, influenced by Evenki.

Another dialect is Dolgan, spoken by about 6500 persons, mainly on the Taimyr peninsula. It differs from the northwestern dialects and has its origin in Tungusic groups who shifted to Yakut at an early stage. They left their settlements on the Vilyuy at the end of the 16th century or later, migrated northward and absorbed parts of the population of the Taimyr peninsula, primarily Nganasans, i.e., speakers of Tavgi Samoyedic, and also further groups. Dolgan thus has both an Evenki and a Nganasan substrate. It still functions as the lingua franca of Taimyr. The present-day Dolgans (self-designation *haka*, corresponding to *saxa*) distinguish themselves from Yakuts and consider their variety a language in its own right. Dolgan differs somewhat from other Yakut varieties in lexical respect, and it also displays a few differences in terms of phonology and grammar. An archaic feature is the absence of the change of initial and final *q* to *x*, e.g., *katun* 'woman' (Yakut *xotun*), *kol* 'shoulder' (Yakut *xol* 'arm'), *atak* 'foot' (Yakut *atax*), *huok* 'nonexisting' (Yakut *suox*). An innovative feature is the development of secondary *s-* into *h-*, e.g., *haka* 'Yakut' (Yakut *saxa*), *hïl* 'year' (Yakut *sïl*), *heri:* 'war' (Yakut *seri:*).

Yamada, Yoshio (1873–1958)

R Washio, University of Tsukuba, Ibaraki, Japan

© 2006 Elsevier Ltd. All rights reserved.

Often referred to as the last scholar in the *Kokugaku* ('national learning') school of thought, Yoshio Yamada made original and lasting contributions to a wide range of fields, including Japanese linguistics, literature, philology, and the history of grammatical studies in Japan. He is best known as the founder of the theory of Japanese grammar named after him, the Yamada Grammar. In his first book, *Nihonbunpōron* ('A theory of Japanese grammar'), Yamada presented for the first time a systematic and well-organized framework in which to describe the facts of Japanese. Using this framework, he wrote some valuable descriptive grammars of Japanese at several stages of its historical developments, including Old, Early Middle, and Middle Japanese. These, together with his highly original works on some specific issues such as honorifics, writing system, and the constructions derived from the Japanese reading of Chinese texts, made pioneering contributions to Japanese linguistics.

Yamada was born in Toyama on May 10, 1873. He left school in his teens and never received formal education in higher educational institutions. He educated himself to be a teacher, first in primary school and then in junior high school. The abovementioned *Nihonbunpōron* was written when he was a junior high school teacher in a remote corner of the country. In 1902, he submitted it to the Ministry of Education for the degree of Doctor of Literature. Tokyo Imperial University was commissioned to assess it, but oddly enough left the matter vague for more than 25 years. It was said then that Yamada's lack of formal education had something to do with it. The title of Litt.D was finally conferred on him in 1929 when he was a professor at Tohoku Imperial University, his retirement only 4 years ahead. Reporting this incident, a newspaper described him as a victim of "academic cliquism." Whether or not he had a degree, however, he had already published by this time some 20 books and 100 articles on Japanese grammar, literature, philology, etc., which had made him an acknowledged authority in such fields.

Yamada also wrote extensively on issues related to Japan's indigenous religion (Shinto) and the history of Japan from a nationalist perspective. For him, the study of the language and classical literature of Japan was only a part – albeit the fundamental part – of the endeavor to throw light on the 'national essence' of Japan. In 1940, Yamada became President of Jingu-Kogakkan, a Shinto-based university. He was appointed to the House of Peers in 1944. He also served as the Director of the Institute for the Compilation of National History. In 1957, he was awarded the Order of Cultural Merit. Yamada died in Sendai on November 20, 1958.

Yang Xiong (53 B.C.–18 A.D.)

H Pan, City University of Hong Kong, Hong Kong, China

© 2006 Elsevier Ltd. All rights reserved.

Yang Xiong (53 B.C.–18 A.D.) was born in a poor family in Shu, a prefecture during the Western Han Dynasty (206 B.C.–25 A.D.), comprising the areas in and around today's city of Chengdu, the capital of Sichuan Province, China. He displayed an inclination for independent thinking and a strong love for literature, even when he was young. He produced a great number of writings in imitation of 'Cifu,' a new style of poetry that came into existence in the State of Chu (today's Hubei and Hunan Provinces) in the Warring States Period. At the age of 41, Yang left his hometown and went to the capital city of China, Chang'an (today's city of Xi'an, the capital of Shaanxi Province), where he was recommended to the emperor, who loved 'Cifu' passionately. One year later, Yang began to work as a literature attendant in the court. With his great talent for linguistic study and the support of the emperor, Yang gave up literature for linguistics and devoted himself heart and soul to the study of dialects. His important linguistic works include *Taixuan* (*Profound theory*), *Fayan* (*The law of speech*), *Xunzhuan* (*Explanation editing*) and *Fangyan* (*Regional dialects*).

Yang occupies a most important place in the history of Chinese linguistics. He was the first to undertake a systematic study of Chinese spoken languages. He often used as his informants soldiers serving in the capital city or visitors from different regions, of different social classes, and with different language backgrounds. He recorded facts about their speech and did his analysis carefully and thoroughly. The result of his 27-year survey was the book *Fangyan*, its full title being *Youxuan Shezhe Juedai Yushi Bieguo Fangyan* (*Unrivalled explanation of the regional dialects by light carriage envoy*).

Fangyan was the first work devoted to dialect vocabulary in the history of Chinese linguistics; it is from the title of this book that the modern word for 'dialect' (*fangyan* – lit. 'regional speech') was derived. For nearly 2000 years, *Fangyan* has been viewed as the model of dialectical analysis in Chinese linguistics. While the original version consisted of 15 volumes, about 9000 Chinese characters in total, the current version is an enlarged edition, with 13 volumes and about 11 900 Chinese characters, including words and expressions covering clothing, utensils, animals, weapons, insects, and worms. Among those dialects recorded in *Fangyan*, the dialects in the State of Qin (roughly today's Shaanxi Province and eastern Gansu Province) and the State of Jin (mainly today's northern part of Shanxi and Hebei Provinces) take up more pages and receive more detailed analyses. They even serve as the basis on which other regional dialects are explained, which suggests that the common tongue of the Han Dynasty might have been developed from the dialects of Qin and Jin.

With its focus on the living, spoken dialects, *Fangyan* serves as a monograph of comparative dialectal vocabulary, with words taken from earlier texts or elicited from contemporary dialect speakers by Yang Xiong himself; the words are defined in terms of the Han standard language and recorded in Chinese characters. Instead of simple lists, the book classifies synonymous words according to their sources and origins. The book also recognizes common words, dialectical words, and ancient words, and explores their mutual relationships, which indeed is a remarkable achievement at that time.

Yang Xiong's work is of great significance from the perspectives of both synchronic and diachronic linguistics. It not only provides a clear picture of the distribution of Han dialects but also shows the changes in meaning of words in regional dialects. It is a exemplary example of language study that takes into consideration both time and regional differences, and also an important source for Chinese exegetical studies and cultural studies.

In style, *Fangyan* is similar to *Erya* (the first dictionary in China), in that they both list groups of so-called synonyms and provide an explanation for each group in the common tongue of the time, although real synonyms are rare and the so-called synonyms often

differ in one way or another. The subtle meaning difference among the synonymous words is the center of attention in *Fangyan*, which makes it fundamentally different from *Erya*, in addition to covering many more regional dialects of the time.

Fangyan is also the first work on dialectology in the world. Not until the late 18th century, namely, more than 1700 years later, did Balas's similar work *A comparative dictionary of languages and dialects in the world* appear in Russian. In Europe, the systematic study of regional dialects, also known as linguistic geography or dialect geography, commenced in the late 19th century, and Georg Wenker from Germany was one of the pioneers. In certain sense, Yang Xiong's *Fangyan* can be regarded as the earliest work on dialect geography in the world.

Yanito

D Levey, Universidad de Cádiz, Cádiz, Spain

© 2006 Elsevier Ltd. All rights reserved.

Yanito (or Llanito) is the name commonly used to refer to the people of Gibraltar as well as their local vernacular. Although various theories exist, it seems likely that it has its etymological origins either in the English name 'Johnny' or alternatively, reflecting the traditional Genoese presence in the British colony, it may be derived from 'Gianni,' the diminutive of the Italian boys' name 'Giovanni.'

Yanito is not an autonomous language as such, and it is seldom found in written form. It is fundamentally a spoken Spanish-dominant variant, which incorporates English lexical and syntactic constituents as well as some unique local lexical items. Although the Spanish/English content ratio may vary from speaker

differ in one way or another. The subtle meaning difference among the synonymous words is the center of attention in *Fangyan*, which makes it fundamentally different from *Erya*, in addition to covering many more regional dialects of the time.

Fangyan is also the first work on dialectology in the world. Not until the late 18th century, namely, more than 1700 years later, did Balas's similar work *A comparative dictionary of languages and dialects in the world* appear in Russian. Yanito

D Levey, Universidad de Cádiz, Cádiz, Spain

© 2006 Elsevier Ltd. All rights reserved.

Yanito (or Llanito) is the name commonly used to refer to the people of Gibraltar as well as their local vernacular. Although various theories exist, it seems likely that it has its etymological origins either in the English name 'Johnny' or alternatively, reflecting the traditional Genoese presence in the British colony, it may be derived from 'Gianni,' the diminutive of the Italian boys' name 'Giovanni.'

Yanito is not an autonomous language as such, and it is seldom found in written form. It is fundamentally a spoken Spanish-dominant variant, which incorporates English lexical and syntactic constituents as well as some unique local lexical items. Although the Spanish/English content ratio may vary from speaker

to speaker, most Gibraltarians will, consciously or unconsciously, alternate between English and Andalusian Spanish in everyday situations.

Code-switching may take place inter-sentencially or intra-sentencially.

> Yanito
> What? Pero . . . I told you, no? No puedo ir shopping porque I have to work late. Sorry, no puedo hablar ahora. Anyway, te llamo esta noche OK?
> English
> What? But . . . I told you, didn't I? I can't go shopping because I have to work late. Sorry, I can't speak now. Anyway I'll phone you tonight, OK?

Although L1 interference and unnatural direct translations may sometimes be present resulting in what is popularly known as 'Spanglish,' the syntactic rules of both languages tend to be respected.

Individual English lexical items, particularly nouns, are commonly introduced in otherwise Spanish utterances. This is often because no direct equivalent exists or its cultural or social nuance cannot be easily or succinctly conveyed. Although British English pronunciation norms tend to be followed, some older borrowings and derivations have been Hispanicized, usually reflecting the local Andalusian pronunciation. Interestingly, several of these words have also found their way across the border and are used in the neighboring Spanish towns of La Linea and San Roque.

- *chinga* = chewing gum
- *liqueribá* = liquorice bar
- *mebli* = marbles
- *el tishella tisha* = teacher

Other English borrowings have taken on a different meaning within the local context. *Pish-pine* (from the English 'pitch pine'), for example, is used locally as an adjective or an adverb to mean 'perfect.'

> Al final todo salió pish-pine.
> In the end everything turned out just fine.

While Spanish and English form the basis of the local lexicon, several borrowings from other languages are also present, reflecting the multicultural makeup of the British colony. These come mainly from Italian (e.g., *pompa* = pump), Arabic (e.g., *flush* = money), and Hebrew (e.g., *ha ham* = boss).

Although Yanito does not hold prestige status, it is not overtly stigmatized either. It is regarded with a certain degree of affection and used by many Gibraltarians as an expression of local identity. However, although the use of Yanito is widespread and considered by many to be a defining characteristic of the local speech community, Gibraltar can not be described as a diglossic speech community. Both English and Andalusian Spanish are very much alive, and speakers may adopt either of the three language forms depending on context, domain, and the interlocutor.

Yarshater, Ehsan (b. 1920)

B Mahmoodi-Bakhtiari, Tehran, Iran

© 2006 Elsevier Ltd. All rights reserved.

A leading figure in Iranian studies, Persian literature and Iranian linguistics, Ehsan Yarshater was born on April 3, 1920 in Hamedân, Western Iran. He studied Persian language and literature, and got a Ph.D. in Persian language and literature in 1947 from Tehran University. His dissertation dealt with Persian poetry under the Timurid Shahrukh (15th century). In the same year, he went to the School of Oriental and African Studies, London University, and studied pre-Islamic Iranian languages and culture with W. B. Henning.

It was in this period when Yarshater adopted a great interest in Iranian linguistics, especially the study of the dialects of northwestern Iran. In 1950, with the encouragement of Henning, he had been able to make brief notes on one of them, especially the one spoken in the southwest of Qazvin, and found a link of related dialects, all greatly endangered. After his employment in the Faculty of Letters at Tehran University, he continued the search for such dialects, which developed into his scholarly lifework. His constant efforts in studying these dialects were a major contribution to Iranian linguistic studies and resulted in the introduction of 'TatiTaleshi' groups of Iranian languages.

During his academic career in Iran, Ehsan Yarshater was engaged in many administrative duties. In 1954, he contributed to the founding the *Bongâh-e Tarjome va Nashr-e Ketâb* (Institute for the Translation and Publication of Books), whose primary aim was to have foreign works of recognized worth translated into Persian by scholars of repute. Under his supervision, a massive contribution was made to the intellectual life of Iran. He was also the vice-president of the *Societé de la Dialectologie Iranienne* (founded in 1956), of which famous Irananologists and linguists such as G. Redard, G. Morgenstierne, and E. Benveniste were active members. This society was responsible for supervising the recording of dialects throughout Iran.

In 1960 he rose to the level of professor of Old Persian and Avestan, and in the same year he was awarded a Ph.D. by London University for his thesis on 'The Tati dialects spoken to the south of Qazvin,' elaborated and published later as *A grammar of southern Tati dialects* (1969). A year later, he was invited to occupy a chair in Iranian studies at Columbia University, New York, which turned out to be his main place of affiliation until his retirement.

In 1966 he established a Center for Iranian Studies at Columbia University, and started editing the *Encyclopedia of Iran and Islam*, which was published in 1975, but was left unfinished. He was also the editor of the third volume of the *Cambridge history of Iran*, comprising the history of the Selucid, the Parthians, and the Sasanians, as well as a volume entitled *Persian literature*.

In 1972, Yarshater started his greatest contribution to Iranian studies: editing the *Encyclopedia Iranica* in the English language, which is no doubt the most comprehensive reference on Iranian culture, languages, literature, and related fields, whose publication still goes on.

Yarshater has a very wide range of research interests, which cannot be recounted here. In the field of linguistics, he is known for his systematic linguistic study of a wide area, which included Tāleshi-speaking districts on the west Caspian coast, Khalkhal and Tārom in Azerbaijan, Kho'in and the Zanjān region, Rudbar, Kuhpaya, and Alamut to the east of Qazvin, and Rāmand to the south of it, with the Sāve and Kāshān Province (like Abuzaydābādi and Abyāna'i), along with some Central Iranian dialects, as well as the study of some important Jewish Iranian languages.

What makes him different from many of the researchers in the field of Iranian linguistics is his exactness and analytical skills in using multiple parameters and his attention to detail in both phonological and morphological issues (like his study of gender in the dialects of the Kāshān area), and his ability to find the minute differences between closely related dialects. His publications are reminiscent of the linguistic tradition set by Andreas, Mann, Zhukovsky, Christensen, and Morgenstierne. His studies cover different aspects of each dialect, with respect to the outer influences and the recent changes, therefore, the data and analysis provided by his works are ideal for linguists interested in the typology of the Iranian

languages. In light of his studies on southern Tati dialects, he discovered that the languages of Azarbaijan in the Middle Ages and pre-modern times were the descendants of the ancient Median language. Also, by studying the Jewish dialects of Tehran, Hamadān, Isfahān, Kāshān, Golpayegān, and other towns, he proved that Western and Central Persia had a language other than Persian, whose traces may be seen in such Jewish dialects.

Yarshater's works are still among the most reliable sources of research on the Iranian languages and are used as the best patterns for serious linguistic studies on this branch of Indo-European languages. He is presently the Director of the Center for Iranian Studies and Hagop Kevorkian Professor Emeritus of Iranian Studies at Columbia University.

Yāska

J C Wright, SOAS, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Yāska's *Nirukta* is one of the two oldest theoretical linguistic texts of ancient India. A largely etymologizing, but basically semantic approach to the exegesis of the most archaic Vedic Sanskrit texts, it complements Pāṇini's grammar of vernacular Sanskrit, for which a date ca. 500 B.C. has been canvassed. With its archaic source material and its detailed critical allusions to even earlier theories, the imperfectly preserved text

of *Nirukta* could be the older of the two. Its coherent account of simile and metaphor, for example, recurs as individual grammatical phenomena scattered throughout Pāṇini. The fact that we are often dependent on Pāṇini's systematic exposition for the key to Yāska's terminology, and that Pāṇini's highly selective use of Vedic material has a different Yajurvedic bias, is no decisive counterargument.

The *Nirukta* incorporates a commentary on much of the *Nighaṇṭu,* an evidently preexisting thesaurus of specifically Vedic vocabulary. This, the model for much later vernacular lexicography, was arranged thematically after the manner of Roget, an idea that may have been inspired by the desire to classify the gods as earthly, atmospheric, or heavenly. A large residue of words are graded only according to their relative ambiguity. For several hundred of its words, *Nirukta* provides at least one characteristic citation, mainly from Ṛgveda, which is rendered into normal Sanskrit where necessary. This gloss is significant, both as showing the extent to which the language had become incomprehensible, and as attesting the often impressionistic interpretations on which all later medieval and modern exegesis rests.

Yāska's preamble undertook to resolve existing controversies regarding semantic theory and the role of etymology in exegesis. He postulated radical finite verbs (described as emphasizing sequential becoming) and derivative substantives (denoting fixed entity or punctual state), together with auxiliary separable prefixes (adding a nuance of transitive action) and interjected particles (including notions of conjunct and disjunct actions). Unfortunately for future exegesis, he had inferred (2.1) that Vedic accidence was unsystematic and, in comparison with strict etymological analysis, negligible as a means of determining word division and purport.

The etymologies rely ultimately on detailed collation of the original poets' own word-associations. Thus the word *grā́van*, 'pressing-stone', is mentioned only cursorily as a variety of 'rock,' and is analyzed primarily in the plural as a class of deities, i.e., as sacred objects that in Vedic poetry could both crush demons (*han-*) and provide a noisy apotropaic accompaniment for the litany (*jar-*), and to which the poets had assigned a 'handler' (*gṛh-*). Using an empirical grasp of Sanskrit phonology, Yāska could then (9.8) derive the word *grā́van* from the root *han-* 'slay' or *gṛ-* 'praise,' or in the end from *gṛhṇāti* 'handles' as in some sense subsuming both *gṛ-* and *han-*. In this instance, using extraneous evidence unavailable to Yāska, we have since found for the word a more cogent etymology (*guru* 'heavy'): but the principles of textual and linguistic analysis on which modern comparative philology rest owe much, via Pāṇini, to Yāska's contention that articulate linguistic meaning (*nirukta*), as well as ritual function, could be extracted from the ancient litany.

That the word *Nirukta* actually specifies etymology, virtually as an end in itself, is a misconception: *nirukta* is the analyzed text, the counterpart (1.15), and no doubt also a presupposition, of Pāṇini's science of word building and sentence construction. For the solution of a Vedic crux, Yāska relied on an examination of the various apparent etymological possibilities for each key word in the sentence, in order to identify senses compatible with his prejudiced assumption of a ritualistic context or, failing that, some mythic allusion. The exegesis was completed by later commentators; but, torn between deference to Yāska and their own predilection for a mystic Vedāntic context, they could add little that is cogent to his renderings. For a more definitive translation, modern scholarship is essentially indebted to the insights (e.g., 2.8) that these renderings provide.

Yemen: Language Situation

J C E Watson, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

The Republic of Yemen is situated in the southeast corner of the Arabian Peninsula, bordering Saudi Arabia to the north and Oman to the east, including the island of Suquṭra and its neighboring islets ʿAbd al-Kūri and Samḥa. Prior to unification on May 22, 1990, the area that is now the Republic of Yemen was two states – the Yemen Arab Republic in the north and the People's Democratic Republic of Yemen in the south. The total population in July of 2004 was estimated at over 20 million. Most Yemenis speak one of many dialects of Yemeni Arabic. A large area in the far southeast of the country, bordering and spreading east into Oman and north into Saudi Arabia, is inhabited by an estimated 100 000 (Simeone-Senelle, 1997: 378) speakers of Mehri, one of six extant South Arabian languages. Two other Modern South Arabian languages are spoken in Yemen: Hobyōt is spoken by less than 100 people living along the southern-most portion of the border with Oman, and Suquṭri, with around 70 000 speakers (1990 census), is spoken on the islands of Suquṭra, ʿAbd al-Kūri, and Samḥa. Over the past couple of decades, immigrants from Somalia have formed Somali-speaking communities along parts of the Yemeni Red Sea coast.

The Arabic dialects spoken within the Republic of Yemen are extremely varied, due, at least partially, to the rugged mountainous terrain that separates groups of people and to the dependence of the isolated groups on traditional means of communication. Dialects in the north can be divided broadly into five dialect areas: the coastal plain (the Tihama), the western mountain range, the central plateau, Ḥugari:yah to the south of Ta'izz, and the desert east. Behnstedt (1985) divided these dialects more specifically into 11 areas. Taken together, the dialects exhibit a huge array of archaic features, particularly in the morphology and vocabulary, with remnants of Old Arabic or of one or more of the Ancient South Arabian languages. The Tihama dialects share the Himyaritic definite article *am-* or *im-*, and, as in many dialects in Saudi Arabia to the north, traces of nunation – usually realized as *-in* and suffixed to nonfinal indefinite nouns and adjectives. In many western mountain range dialects, the perfect tense verb ending for first singular and second persons is *-k(V)*, as opposed to *-t(V)*, as in *qul-k* 'I said' versus Central Plateau *gul-t*; this is a morphological feature that almost certainly goes back to one of the Ancient South Arabian languages. The dialects of the Ḥugari:yah maintain the vocalic endings for first and second masculine singular persons in the perfect verb, as in *qult-u* 'I said' and *qult-a* 'you (masculine singular) said,' endings that have long disappeared, if they ever existed, from most other modern dialects of Arabic. Lexical items that are reflexes of Ancient South Arabian include function words, such as the Ḥugari:yah term *da/daw* 'no' and the relative pronoun *ḏi:*, the an-Naḏi:r/Ra:ziḥ (spoken in the northwest mountain area) term *si:* 'to, until,' and many agricultural and architectural content words, such as the Ṣaᶜdah region terms *lahj* 'window' and *xalwah* 'room' (Behnstedt, 1987a: 106–107) and the San'ani terms *mawṯar* 'foundations' and *ᶜari:m* 'dyke.' The allophonic lateral (or, for an-Naḏi:r/Ra:ziḥ, retroflex tʃ (Behnstedt, 1987a,b)) realization of Ḍa:d is phonologically archaic; this realization was described for Classical Arabic by Si:bawayhi in the 8th century C.E., and is now found in dialects spoken both in the far south (Ghaylḥabba:n; see Habtour (1989)) and in the far north (an-Naḏi:r/Ra:ziḥ; see Behnstedt (1985, 1987a,b), Shelagh Weir and Bonnie Glover-Stalls, personal communication).

Geographical isolation leads not only to maintenance of archaic features, but also to grammaticalizations and isolated innovations based on analogy. The an-Naḏi:r/Ra:ziḥ dialect, for example, is marked by its large number of grammaticalized particles and is the only recorded Arabic dialect in which independent pronouns for second persons have developed from dependent pronouns, as in *ak* 'you (masculine singular),' *ać* 'you (feminine singular),' *akkum* 'you (masculine plural),' and *akkun* 'you (feminine plural)' (Behnstedt, 1985, 1987a,b).

Yiddish, a Germanic language spoken by the Jews of Central and Eastern Europe (Ashkenazim) and in the Ashkenazic diaspora around the world, includes significant Semitic and Slavic components as well as its Germanic base. It is one of a number of Jewish languages created on the basis of the coterritorial non-Jewish language (cf. Judaeo-Arabic, Judaeo-Persian, Judezmo [Ladino], etc.). Of all such languages, it achieved the widest range of functions, the most highly developed network of institutions and the largest number of speakers.

Orthography

Like all Jewish languages, Yiddish is written in the Hebrew alphabet. Unlike Hebrew, which except for special purposes is normally written without vowel symbols, Yiddish has adapted certain Hebrew letters (sometimes in combination with Hebrew subscript or superscript vowel symbols) to represent vowels. Words and morphemes of Semitic (Hebrew and Aramaic) origin are for the most part spelled as they are in the source languages, while words of Germanic, Slavic, and other origins are spelled in a broadly phonetic manner. The orthography is superdialectal, which permits its use by speakers of the standard language (the phonetics of which is based largely on Northeastern Yiddish) as well as by speakers of dialects, which most strongly differ from the standard and one another in their realization of the vowels. In the Soviet Union, the official orthography for Yiddish 'naturalized' the Semitic component, eliminating the traditional Hebrew and Aramaic spellings in favor of the kind of phonetic representations used elsewhere for the non-Semitic component. Soviet orthography also mandated standardized representations for elements that show dialectal variation, e.g., orthographic *oyf* was spelled *af* as a preposition and *uf* as a prefix. (The standard scholarly transcription for Yiddish is the system developed by the YIVO Institute for Jewish Research [originally in pre-1939 Wilno, Poland, now in New York].)

Phonology

The phonemic inventory of standard Yiddish consists of eight vocalic segments (five oral vowels and three diphthongs) and twenty-nine consonantal segments (some of which play only a marginal role). The oral vowels are *i, e, a, o*, and *u*, realized phonetically as [i], [ɛ], [ɐ], [ɔ], and [ʊ]; the diphthongs are *ey*, *ay*, and *oy*. The basic consonantal inventory contains voiced and voiceless bilabial, dental, and velar stops; bilabial, dental, and palatal nasals; voiced and voiceless labiodental, dental, and alveolar fricatives; a voiceless velar fricative and a voiced laryngeal fricative; voiceless dental and alveolar affricates; a dental and a palatal lateral; a palatal glide; and an /r/ that can be pronounced as a uvular (most speakers) or dental trill. Voiced dental and alveolar affricates, and – regionally – palatal (or palatalized) versions of /t/, /d/, /s/, and /z/ play a somewhat marginal role in the phonological system. The resonants /l/ and /n/ can be syllabic, as can the positional variants of /n/, [m] (in word-final position after /b/ or /p/) and [ŋ] (in word-final position after /k/ or /g/).

As in Slavic, Yiddish obstruents assimilate (generally regressively) with respect to voice, but /v/ does not cause voicing in a preceding voiceless obstruent. Word-final obstruents do not (as in Slavic or German) lose voicing before pause. There is, however, evidence of such devoicing being operative in an earlier stage of the language, e.g., *hunt* 'dog' vs. *briv* 'letter' (cf. German *Hund* with final [t] and *Brief* with final [f]).

Word stress tends toward the penultimate, but words of Germanic origin are often stressed on the initial root syllable, and words of Slavic origin often retain the stress of the source language. Posttonic vowels are generally reduced.

Morphology

Three noun genders (masculine, feminine, neuter) are distinguished in the singular by agreeing forms of the definite article and attributive adjectives, as well as by pronominal reference. Northeastern Yiddish, however, like the neighboring Lithuanian language, has lost the neuter gender. There are no gender distinctions in the plural.

Yiddish, a Germanic language spoken by the Jews of Central and Eastern Europe (Ashkenazim) and in the Ashkenazic diaspora around the world, includes significant Semitic and Slavic components as well as its Germanic base. It is one of a number of Jewish languages created on the basis of the coterritorial non-Jewish language (cf. Judaeo-Arabic, Judaeo-Persian, Judezmo [Ladino], etc.). Of all such languages, it achieved the widest range of functions, the most highly developed network of institutions and the largest number of speakers.

Orthography

Like all Jewish languages, Yiddish is written in the Hebrew alphabet. Unlike Hebrew, which except for special purposes is normally written without vowel symbols, Yiddish has adapted certain Hebrew letters (sometimes in combination with Hebrew subscript or superscript vowel symbols) to represent vowels. Words and morphemes of Semitic (Hebrew and Aramaic) origin are for the most part spelled as they are in the source languages, while words of Germanic, Slavic, and other origins are spelled in a broadly phonetic manner. The orthography is superdialectal, which permits its use by speakers of the standard language (the phonetics of which is based largely on Northeastern Yiddish) as well as by speakers of dialects, which most strongly differ from the standard and one another in their realization of the vowels. In the Soviet Union, the official orthography for Yiddish 'naturalized' the Semitic component, eliminating the traditional Hebrew and Aramaic spellings in favor of the kind of phonetic representations used elsewhere for the non-Semitic component. Soviet orthography also mandated standardized representations for elements that show dialectal variation, e.g., orthographic *oyf* was spelled *af* as a preposition and *uf* as a prefix. (The standard scholarly transcription for Yiddish is the system developed by the YIVO Institute for Jewish Research [originally in pre-1939 Wilno, Poland, now in New York].)

Phonology

The phonemic inventory of standard Yiddish consists of eight vocalic segments (five oral vowels and three diphthongs) and twenty-nine consonantal segments (some of which play only a marginal role). The oral vowels are *i, e, a, o*, and *u*, realized phonetically as [i], [ɛ], [ɐ], [ɔ], and [ʊ]; the diphthongs are *ey*, *ay*, and *oy*. The basic consonantal inventory contains voiced and voiceless bilabial, dental, and velar stops; bilabial, dental, and palatal nasals; voiced and voiceless labiodental, dental, and alveolar fricatives; a voiceless velar fricative and a voiced laryngeal fricative; voiceless dental and alveolar affricates; a dental and a palatal lateral; a palatal glide; and an /r/ that can be pronounced as a uvular (most speakers) or dental trill. Voiced dental and alveolar affricates, and – regionally – palatal (or palatalized) versions of /t/, /d/, /s/, and /z/ play a somewhat marginal role in the phonological system. The resonants /l/ and /n/ can be syllabic, as can the positional variants of /n/, [m] (in word-final position after /b/ or /p/) and [ŋ] (in word-final position after /k/ or /g/).

As in Slavic, Yiddish obstruents assimilate (generally regressively) with respect to voice, but /v/ does not cause voicing in a preceding voiceless obstruent. Word-final obstruents do not (as in Slavic or German) lose voicing before pause. There is, however, evidence of such devoicing being operative in an earlier stage of the language, e.g., *hunt* 'dog' vs. *briv* 'letter' (cf. German *Hund* with final [t] and *Brief* with final [f]).

Word stress tends toward the penultimate, but words of Germanic origin are often stressed on the initial root syllable, and words of Slavic origin often retain the stress of the source language. Posttonic vowels are generally reduced.

Morphology

Three noun genders (masculine, feminine, neuter) are distinguished in the singular by agreeing forms of the definite article and attributive adjectives, as well as by pronominal reference. Northeastern Yiddish, however, like the neighboring Lithuanian language, has lost the neuter gender. There are no gender distinctions in the plural.

Nouns are pluralized by means of several endings, mostly independent of gender: *-n* or its variant *-en*, *-er,* zero (Germanic in origin); *-s* (Romance in origin); *-im*, *-es* (Hebrew in origin). The Germanic and Hebrew suffixes may be accompanied by vowel changes in the stem; the same changes take place in suffixal derivation, e.g., in diminutive formation (cf. *barg* 'mountain,' *berg* 'mountains,' *bergl* 'hill'; *hoyz* 'house,' *hayzer* 'houses,' *hayzl* 'little house').

The definite article, attributive adjectives, and personal pronouns distinguish nominative, accusative, and dative case forms (with extensive syncretism) in the singular (pronouns also in the plural); personal names and a few common nouns can add *-(e)n* to indicate the accusative or dative singular and *-(e)s* to mark a possessive form. Agreeing elements have the same form for dative and possessive. Predicate adjectives occur either as a bare stem or with the indefinite article and a gender ending: *zi iz yung* 'she is young' vs. *zi iz a yunge* 'she is a young one,' parallel to Russian constructions with short- and long-form adjectives (*ona moloda* vs. *ona molodaia*). Adverbs have the same form as the stem of the corresponding adjective.

Yiddish verbs have synthetic forms for the present tense and analytic forms for the past and future tenses. The future is formed by combining the conjugated auxiliary *veln* with the infinitive; the past is formed by combining the auxiliaries *hobn* 'have' or *zayn* 'be' with the past participle. Conditional and subjunctive moods are also formed with auxiliaries: *voltn* (with the past participle) for the former and *zoln* 'should' (with the infinitive) for the latter. The auxiliary *flegn* 'used to' combines with infinitives to express iterativity in the past. A large number of periphrastic verbs combine one of several auxiliaries with an invariable element, often a Hebrew verbal form (e.g., *mekane zayn* 'be envious'; *moyre hobn* 'be afraid, fear'; *vey ton* 'hurt'; *geboyrn vern* 'be born').

Yiddish verbs may be combined with a variety of stressed adverbial complements that are prefixed to the infinitive and participles, but follow the inflected verb as a separate word in the present tense and the imperative (e.g., *avekgeyn* 'to go away,' *ikh bin avekgegangen* 'I went away' vs. *ikh gey avek* 'I'm going away,' *gey avek!* 'go away!'). Under the influence of Slavic verbal systems, some of these inherited Germanic verbal complements are used to express aspectual or Aktionsart meanings, in ways that differ both from the Germanic and Slavic systems. Yiddish also makes broad use of the so-called stem construction, which combines an auxiliary (usually *gebn* 'give' or *ton* 'do') with the indefinite article and an invariant verbal stem to create a semelfactive meaning: *gebn a kuk* 'take a look,' *a trakht ton* 'give a bit of thought.'

Syntax

Yiddish is a verb-second language, with the inflected verb serving as the second clause constituent. In a complex sentence, however, an initial clause can occupy the first constituent position and the verb will therefore occupy the first position in the second clause: cf. *er vet farshteyn* 'he will understand' vs. *az er vet zayn elter, vet er farshteyn* 'when he is [will be] older, he will understand.' The verb can also occupy the first position in a clause or sentence that follows as an implied consequence of a preceding clause or sentence, e.g., *der tate iz geshtorbn, bin ikh geblibn aleyn* 'my [the] father died, [so] I was left all alone.' Interrogative elements (the particle *tsi* that introduces yes-no questions, pronouns, adverbs) count as the first constituent in a direct question but not in an indirect question: cf. *vos hot zi geshribn?* 'what has she written?' vs. *ikh veys nit, vos zi hot geshribn* 'I don't know what she has written.'

Aside from the verb-second requirement, word order is relatively free and is available to express such discourse functions as emphasis, contrast, topic vs. comment. In order to move a subject to a more emphatic position without violating the verb-second principle, the neuter pronoun *es* (or its variants in this function *se, s*) serves as a dummy occupying the first constituent position, e.g., *es iz tsu mir gekumen a kuzine* 'a cousin came to me.'

Like its Slavic counterparts (but unlike the situation in Germanic), the reflexive pronoun *zikh* serves for all persons and numbers. It also serves both as the full accusative/genitive and dative of the reflexive/reciprocal pronoun (cf. Polish *siebie/sobie*) and as the enclitic form that occurs with verbs in a variety of functions (cf. Polish *sie*). Verbs with *zikh* can express, among other things, a kind of middle voice (e.g., *vashn zikh* 'wash/wash up/get washed') and also an intransitive verb with an unaccusative subject (e.g., *der vinter heybt zikh on* 'winter is beginning'). Following Slavic models, prefixed (or complemented) verbs with *zikh* express various Aktionsart meanings (e.g., *tselakhn zikh* 'burst out laughing'; cf. Russian *rassmeiat'sia*).

Yiddish does not drop subject pronouns, although some contracted forms are used in speech (*kh* for *ikh* 'I,' *r* for *er* 'he'). Second-person plural pronouns and verb forms are used in nonfamiliar address.

Lexicon

Although the basic stock of Yiddish vocabulary is Germanic in origin, there is also a large Semitic component (from Hebrew and Aramaic, known collectively in Yiddish as *loshn-koydesh* 'the language of

holiness'), which may reach as much as 15% or more depending on style and register. The significant Slavic component comes primarily from Polish, Ukrainian, and Belarusian, and there are traces of old Romance influences. Many Greek- and Latin-based internationalisms entered the language in the 19th and 20th centuries, often via one Slavic language or another. The Germanic, Semitic, Slavic, and other elements were phonologically and morphologically integrated into the Yiddish linguistic system, often being creatively reworked. The verb *balebatevn* 'keep house; manage; bully,' for example, contains two Hebrew roots (meaning 'master of the house'), a Slavic suffix used to derived verbs from foreign roots (cf. Polish-*owa*-), and a Germanic infinitival ending. Calques were created both on the word level (see the above examples of verbal prefixation) and on the phrase level. A colloquial phrase meaning 'put in jail,' *araynzetsn in koze*, borrows the Polish slang term for 'jail,' *koza*, literally, 'goat' and uses Germanic elements (verbal complement *arayn*, root *zets*-, infinitive ending *-n*, preposition *in*) to calque the entire Polish phrase *wsadzić do kozy*. A more elaborate version replaces the Germanic verbal root with a Semitic one, and the Polish slang term with the Aramaic-origin phrase *khad-gadye* 'a single kid,' giving *araynyashvenen in khad-gadye*.

Although many words from the Semitic component are related to Jewish religious life, many are not (e.g., *khaver* 'friend; [political] comrade'; *balebos* 'master of the house; boss'), and there is no neat correspondence between the origins of words and their sphere of application. So, for example, the verb meaning 'say a blessing' is *bentshn*, which is of Romance origin (ultimately related to Latin *benedicere*), while the word *got* 'God' is from the Germanic component (and has an affective form with a Slavic suffix, *gotenyu*). Most kinship terms are of Germanic origin, but *zeyde* 'grandfather' and *bobe* 'grandmother' come from the Slavic component.

History

Yiddish is generally assumed to have begun to develop as a distinct linguistic variety around the year 1000 C.E. The long-dominant theory of origins (connected with the work of Max Weinreich) attributes this development to the migration of Jewish speakers of Old French and/or Old Italian, who were literate in Hebrew/Aramaic, into the Rhine Valley, where they encountered Germanic speakers. In recent years, scholars have questioned parts of this theory, suggesting Northern Italy or Bavaria as the point of initial contact, arguing that Yiddish developed as a relexification with Germanic materials of a kind of Judaeo-Slavic (Paul Wexler) or proposing that Yiddish began with contacts between Aramaic-speaking Jews from the Middle East and Germanic speakers (Dovid Katz).

As Jews moved eastward, they settled among speakers of Slavic languages (first Czech, then Polish, later Ukrainian and Belarusian). From around 1500 and until World War II, the majority of Yiddish speakers inhabited the largely Slavic-speaking lands of Central and Eastern Europe. In addition to the Yiddish-speaking religious institutions (educational, social, etc.) that functioned throughout that territory, there existed during the 1920s and 1930s in Poland and (until the mid-1930s) in the Soviet Union a wide array of educational, cultural, social, and political institutions with Yiddish as their language of instruction, publication, daily business, etc. The Nazi annihilation of European Jewry, together with assimilation (voluntary or forced) to the dominant cultures in the Soviet Union and the overseas lands of the Eastern European Jewish diaspora, has led to a great diminution in the number of speakers of Yiddish. Yiddish is alive today among a decreasing number of elderly Jews of East European origin and in certain traditionalist (mostly Hasidic) communities in North America, England, and Israel, where it serves as the principal vernacular. It is also cultivated by an unknown number of relatively young, largely secular, Jews (and some non-Jews), who are devoted to keeping the language and culture alive.

The oldest dated Yiddish text (1272) is a sentence written in a prayer book in Worms, Germany. The first printed text is a Yiddish translation of a Hebrew prayer included in a 1526 Prague haggadah, and the first Yiddish book is a Hebrew–Yiddish Bible concordance published in Cracow in 1534 or 1535.

Dialectology

The dialect map of Yiddish is divided into Western and Eastern Yiddish, with the latter subdivided into Central (Polish), Northeastern (Lithuanian), and Southeastern (Ukrainian) Yiddish. Western Yiddish is defined roughly as Yiddish spoken west of the 1939 Polish-German border; it is the descendent of the earliest Yiddish, and even by 1939 had largely been replaced by German, although some speakers continued to use it in such areas as Alsace, Switzerland, and Slovakia. Linguistically, the Yiddish dialect continuum is divided on the basis of the development of certain proto-Yiddish vowels. In particular, the phrase 'to buy meat' (*koyfn fleysh* in Standard Yiddish) would be *ka:fn fla:sh* (with long vowels) in WY, *koyfn flaysh* in CY, *keyfn fleysh* in NEY and *koyfn fleysh* in SEY. Standard Yiddish (which is, strictly

speaking, Standard Eastern Yiddish) is largely based on NEY as far as its vocalism is concerned, although in the case of the diphthong of 'to buy,' the standardizers chose the variant common to CY and SEY (*oy*) rather than the NEY variant (*ey*). The more usual choice of vowel for the standard is reflected in a phrase like 'one day': Standard and NEY *eyn tog*, CY *ayn tug*, SEY *eyn tug*.

Standard Yiddish, like NEY, but unlike CY and SEY, does not distinguish vowel length. It does, however, distinguish dental and alveolar fricatives and affricates, like CY and SEY, but unlike NEY. NEY also has no neuter gender, unlike the other Yiddish dialects (and the standard language). A detailed account of Yiddish dialect phenomena is presented in the multivolume *Language and culture atlas of Ashkenazic Jewry*, three volumes of which have been published as of 2004.

Yiddish Lexicography

K Hoge, Oxford University, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

The history of Yiddish lexicography is inextricably linked to the sociocultural history of the speakers of Yiddish. Yiddish dictionaries, in both their intended readership and method of compilation, chart the demographic and attitudinal changes within the Yiddish speech community. This brief overview classifies the material along the categories of dictionary users and situations of dictionary use.

Users of Yiddish dictionaries may be either native speakers of Yiddish or speakers of a second language who seek access to Yiddish texts or spoken discourse. The beginnings of Yiddish lexicography rest with the former. Interlinear glosses of Hebrew and Aramaic words appear in manuscripts of the 12th and 13th centuries, among them around 30 glosses in the Bible and Talmud commentaries by Rabbi Shlomo Yitzhaki (Rashi, 1040–1105). As with English, interlinear glosses evolved into separate word lists, which, as they grew in size, created the need for a classificatory system, giving rise to Bible concordances (e.g., *Mirkeves hamishne*, Cracow 1534) and thesauri (e.g., *Khinekh kotn*, Cracow 1640), and ultimately to the first multilingual dictionaries, such as Elye Bokher's *Tishbi* (Basle 1526), a Hebrew-Aramaic-Italian-Yiddish dictionary of 712 entries (the numerical value of the Hebrew letters *tishbi*). Elye Bokher also compiled the first dictionary that used Yiddish as the source language, the Yiddish-Hebrew-Latin-German dictionary *Shmoys dvorim* (Isnae 1542).

From the 16th century onwards, Yiddish lexicographical works appear in Germany, which are aimed at a non-Jewish, rather than a Jewish, Yiddish-speaking readership. These include scholarly treatises by Christian Hebraists (e.g., Boeschenstain's *Elementale introductorium in hebreas literas teutonice & hebraice legendas*, Augsburg 1514), practical

From the 16th century onwards, Yiddish lexicographical works appear in Germany, which are aimed at a non-Jewish, rather than a Jewish, Yiddish-speaking readership. These include scholarly treatises by Christian Hebraists (e.g., Boeschenstain's *Elementale introductorium in hebreas literas teutonice & hebraice legendas*, Augsburg 1514), practical

manuals for businessmen in need of a rudimentary knowledge of Yiddish (e.g., Helicz's *Elemental / oder lesebüchlen*, Hundesfeld 1543), dictionaries written by missionaries (e.g., Callenberg's *Jüdischteutsches Wörterbüchlein*, Halle 1736), antisemites (e.g., Bibliophilus' *Jüdischer Sprach-Meister oder Hebräisch-Teutsches Wörter-Buch*, Frankfurt and Leipzig 1742) or police chiefs interested in Yiddish as one of the source languages for the German thieves' cant Rotwelsch (e.g., Avé-Lallemant's *Das deutsche Gaunerthum*, Leipzig 1858–1862).

What unites the early dictionaries produced for Yiddish speakers and those for non-Jewish users is the situation of dictionary use. The reference needs of both groups are primarily receptive. While Yiddish speakers require help in the reading of Hebrew-Aramaic texts, non-Jews look for material to aid their aural and reading comprehension of a language that is most notably distinguished from their own by its Hebrew-Aramaic component.

It is in the era of modern Yiddish lexicography that the two user groups diverge in their situations of dictionary use. For native speakers of Yiddish, Lifshits' Russian-Yiddish and Yiddish-Russian dictionaries (Zhitomir 1869 and 1876) and Harkavy's Yiddish-English (New York 1898) and Yiddish-English-Hebrew dictionaries (New York 1925, 2nd edn. 1928) may serve productive reference needs, enabling first-to-second language translation and contributing to the speakers' acculturation in an immigrant society (cf. Harkavy's appendix of Yiddish personal names and their English equivalents, provided so that readers can anglicize their names 'in the proper way'). At the same time, modern Yiddish lexicographical efforts, both normative, as Uriel Weinreich's *Modern English-Yiddish Yiddish-English dictionary* (New York 1968), and descriptive, as Stutchkoff's *Thesaurus of the Yiddish language* (New York 1950) and, in particular, the monolingual *Great dictionary of the Yiddish language* (New York, Jerusalem 1961–1980, vols 1–4), are felt to raise the prestige of the Yiddish language and thus serve an important sociolinguistic function.

For non-native Yiddish speakers, these functions are absent. Their primary situation of dictionary use remains receptive. As the number of native Yiddish speakers steadily decreases and becomes confined to members of the ultra-orthodox communities, the dictionary can only provide a tool for the comprehension of Yiddish literary and journalistic texts, as is given as the objective in the most recent Yiddish dictionary (*Dictionnaire yiddish-français*, Paris 2002). The development of Yiddish lexicography from dictionaries for speakers of the source language to dictionaries for speakers of the target language mirrors the external history of Yiddish. It remains to be seen what lexicographical needs will emerge among today's ultra-orthodox Yiddish-speaking communities.

Yoruba

K Owolabi, University of Ibadan, Ibadan, Nigeria

© 2006 Elsevier Ltd. All rights reserved.

Location and Number of Speakers

Yoruba is spoken as a first language in Nigeria in virtually all areas in the states of Èkìtì, Lagos, Ògùn, Òǹdó, Ọ̀ṣun, and Ọ̀yọ́, and in most of the areas in Kwara and Kogi states; Yoruba is a second language in some areas of the Delta and Edo states as well as in the non-Yoruba-speaking areas of the Kwara and Kogi states (see Figure 1). Outside Nigeria, there are Yoruba-speaking communities in the republics of Togo and Benin, where, in the southern part, Yoruba, Aja, and Fon are the three dominant indigenous languages (see Adeniran, 2004: 437). Based on the 1991 census, the number of speakers of Yoruba as a first or second language in Nigeria alone is about 19 000 000.

Genetic Relationship and History

Yoruba is a member of the Defoid language group within the Benue-Congo subgroup of the Niger-Congo family (see Williamson, 1989: 20, 26; Capo, 1989: 275–290). Although the origin of the term 'Yoruba' is still shrouded in mystery, some late 20th-century (historical/comparative) linguists have suggested that the dispersal center for the Yoruba people is around the southwest area of the confluence of the Niger and Benue rivers in Nigeria (see Akinkugbe, 1978; Williamson, 1989: 270).

Earliest Written Record

The Yoruba writing system uses the Roman alphabet, augmented by letters with diacritics. The earliest written records include the vocabularies compiled by Thomas Bowdich in 1819 (including words for the numerals 1–10), by Hannah Kilham (1828), and by Wilhelm Koelle (1854; *see* **Koelle, Sigismund Wilhelm (1823–1902)**). The teaching booklets of John Raban (1830–1832) and the vocabularies and grammars of Samuel Crowther (1843, 1852; *see* **Crowther, Samuel Ajayi (1806/08-1891)**) contributed further to the written record. Publication of Crowther's school primer (1849; written wholly in Yoruba) was followed by the various translation works in the Old and the New Testaments by Crowther (1950–1956) and by Thomas King (1957–1961). The first vernacular periodical, the newspaper *Ìwé Ìròhìn*, was printed at Abẹokuta from 1859 to 1867 (see, in particular, Hair (1967)).

Individual Characteristics

Yoruba has a number of characteristics that appear unique to Yoruba or are not widespread among its genetic relatives.

Syntactic Characteristics

Noun Classes, Gender System, and Number Yoruba has no noun class or grammatical gender. There are no separate noun forms to distinguish singular from plural. However, when necessary, plurality can be marked by using some (pro)nominal forms before nouns, or by using certain demonstratives, as well as by reduplicating adjectives after nouns.

Possessive Noun–Noun Constructions In a sentence, the second noun in a possessive noun–noun construction can be focused by front shifting it, with its original position being occupied by the appropriate pronoun qualifier. After certain verbs, it is also possible to permute the constituent nouns with the particle *ní* obligatorily intervening (see Owolabi, 1976: 40–43).

Past and Present Actions Action verbs generally convey past action, whereas stative verbs convey past or present action.

Verbal Constructions There are verbal constructions in which subject and object nouns can switch positions with little or no difference in meaning, and verbal constructions in which the verbs are repeated after their objects; in addition, some verbal constructions contain verbs that are used for asking questions, verbs that are negative in meaning, or verbs that obligatorily select the particle *ní* (see Awobuluyi, 1978: 53–62).

Morphological Characteristics

In order to form morphologically complex nouns, certain prefixes (for example, *à-*, *è-*, *o-*, *i-*, and *ài-*) that are usually attached to roots that are verbs or verb phrases, and sometimes to ideophonic adjectives, cannot be combined. However, the prefixes *oní-* and *oni-*, which are attached to nouns or noun phrases, can be combined and can also combine with the former class of prefixes, resulting in nouns that denote emphasis (see Owolabi, 1995: 93–102).

Phonetic/Phonological Characteristics

Vowel Co-occurrence Restrictions and Vowel Elision Yoruba operates a partial system of vowel harmony in which the set /e, o/ mutually excludes the set /ɛ ɔ/ in

Figure 1 Nigerian states in which Yoruba is spoken as a first or second language. Key to states: 1, Èkìtì; 2, Lagos; 3, Ògùn; 4, Òǹdó; 5, Ọ̀ṣun; 6, Ọ̀yọ́; 7, Kogi; 8, Kwara; 9, Delta; 10, Edo.

Figure 2 Phonetic groupings of Yoruba consonants and vowels. Tones are indicated by diacritical marks: high (ˊ), mid (¯), and low (ˋ).

polysyllabic underived words. Also, in words with a vowel$_1$-consonant-vowel$_2$ (V_1-C-V_2) pattern, neither the nasalized vowels nor /u/ can occur as V_1. Vowel elision, resulting in contractions, is quite erratic apart from the relatively predictable elision of the vowel /i/, the initial vowel of the second noun of noun–noun combinations, or the vowels of the standard forms of words in combination with the dialectal forms (see Bamgbọṣe, 1989). Figure 2 shows the phonetic groupings of Yoruba consonants and vowels; tones are indicated by diacritical marks: high (ˊ), mid (¯), and low (ˋ).

The Assimilated Low Tone In addition to the high, mid, and low tones in Yoruba, a tonal feature referred to as 'the assimilated low tone' occurs when a low tone disappears in certain contracted expressions or in some single polysyllabic words, but its influence is still felt on the following syllable (see Bamgbọṣe, 1966).

Restriction on the Occurrence of the High Tone The high tone never occurs on V_1 in words of V_1-C-V_2 pattern.

Tones of Pronouns With the exception of the second-person plural pronoun object, the lexical tones of the verbs determine the tones of all pronoun objects. Similarly, the tones of some subject pronouns vary before the verbal particle *ń*.

Other Characteristics

Various semantic effects (e.g., emphasis, anger, and anxiety) can be achieved by employing the devices of reduplication, prefixation, and vowel lengthening, or

by using 'intensifiers.' Focusing whole sentences apart from sentence constituents is also common. The following sentence provides an example of the Yoruba language:

> Alákàá ni ilé ẹ̀ wó, tí olè sì kó mi ní ẹrù, ṣùgbọ́n ó dún mí pé Olú jó, jó, jó ni lẹ́yìn ìṣẹ̀lẹ̀ wọ̀nyí, èyí tó mú kí àwọn ọlọ́mọ̀wé ọ̀rẹ́ Olú rò pé kò fẹ́ èmi àti Alàkàá fẹ́ ọrọ̀, àmọ́ láìpẹ́, Alákàá yóò ralẹ́ tuntun, yóò sì rọkọ̀ pẹ̀lú.
>
> It was Alákàá's house that fell while thieves stole my property, but it pained me that what Olú did was to really dance after these incidents, which made Olú's educated friends think that he isn't happy to see Alákàá and me prosper, however, Alákàá will soon purchase a new house and a vehicle as well.

Note that *ẹ̀* occupies the original position of the front-shifted noun *Alákàá*, and that *mi ní ẹrù* is a possessive construction resulting from permutation. In *Alákàá* (from '*oní àká*'), the influence of the assimilated low tone is felt; *mi* has a high tone after the low-tone verb *dùn*, but a mid tone after the high-tone verb *kó*. For emphasis, *jó* is reduplicated and *Alákàá* and the phrase beginning with *ṣùgbọ́n* are focused by placing the focus marker *ni* after them. Plurality is indicated by *wọ̀nyí* and *àwọn*, *ọlọ́mọ̀wé* comprises the verb phrase *mọ̀wé* and the prefixes *ọ̀-* and *oní-*, and *fẹ́* is repeated after *èmi àti Alákàá*. The 'a' of *rà* is retained in the verb–noun contraction *ralẹ́* (from *ra ilé* 'purchase a house') but is elided in *rọkọ̀* (from *ra ọkọ̀* 'purchase a vehicle'). A phonemic transcription of the sentence is as follows:

> ālá'ká lĩ̄ īlé ẹ̀ wó, tí ōlè si kó mĩ̄ lí ẽrù, ʃùgbɔ̃́ ó dṹ mí kpé ōlú jó jó jó lĩ̄ lẹ́ʃĩ̀ ìʃèlẹ̀ wɔ̃̀jí, èjí tó mṹ kí àwɔ̃̄ ɔ̄lɔ̀mɔ̃̀wé ɔ̀rẹ́ ōlú rò kpé kò fẹ́ èmĩ̄ àtī ālá'ká fẹ́ ɔ̄rɔ̀, àmɔ̃́ láìkpẹ́, ālá'ká jóò rālé tũ̄tũ̄, jóò sì rɔ̄kɔ̀ kpèlú.

Other Points of Relevance

The Yoruba language comprises about 20 dialects. There is also a form of Yoruba popularly referred to as Standard Yoruba. In all of the Nigerian states in which Yoruba is spoken natively, the Standard Yoruba and the Yoruba dialects are spoken. However, a diglossic situation exists where the Standard Yoruba is the high variety and the dialects are the low variety, although the use of some of the dialects in publications, broadcasts, and native courts (in particular) is increasing. The variety of Yoruba described in this article is Standard Yoruba. Yoruba vocabularies occur in poetic recitations associated with rituals and cults in Brazil as well as in Sierra Leone, where the influence of Yoruba is also felt in Krio loanwords and personal names.

Yoruba is one of the three major languages in Nigeria (the other two are Hausa and Igbo). It is taught as a subject at the primary, secondary, and tertiary levels. At least eight universities in Nigeria offer first degree and/or higher degree courses in Yoruba. Literature in the language is also very extensive. According to government policy, in the states in which Hausa, Igbo, or Yoruba is not a mother tongue, one of these three languages is a compulsory subject at secondary school level. The three languages are also to be used in the National Assembly in addition to English, and one of the state assemblies in the Yoruba-speaking states is currently using Yoruba in the same way. Similarly, the Nigerian federal government has embarked on the translation of the 1999 constitution of the Federal Republic of Nigeria into Yoruba and the other two major Nigerian languages (Hausa and Igbo), in order to facilitate the usage of these languages in the domain of legislation.

A Yoruba metalanguage (available in two volumes) has facilitated the use of Yoruba for writing textbooks and as a medium for teaching the language at all levels of education, whereas the Six-year Primary Project at the Ọbafẹmi Awolọwọ University (formerly the University of Ifẹ), in Ile-Ifẹ, Ọ̀ṣun State, aims at demonstrating that all subjects can be taught in Yoruba at the primary level.

In the neighboring Republic of Benin, the Yoruba, Aja, and Fon languages are studied at the university level; Yoruba was adopted (along with Aja, Fon, Bariba, Bendi, and Waama) as an official language of the National Assembly in 1983 (see Adeniran, 2004: 437, 442).

Young, Thomas (1773–1829)

E Shay, University of Colorado, Boulder, CO, USA

© 2006 Elsevier Ltd. All rights reserved.

Thomas Young, nicknamed 'Phenomenon' by his contemporaries at Cambridge, was born June 13, 1773, in Milverton, Somerset (England), the youngest child of Quaker parents. By his teens, the precocious Young was well acquainted with a number of classical and modern languages, though accounts differ as to how many. He also excelled in natural sciences and mathematics. Young began studying medicine in London at age 19, moving to Edinburgh in 1794 and completing his medical studies at Göttingen in 1796. In 1794, still a student, Young was elected fellow of the Royal Society. In 1797 a bequest from a great-uncle enabled him to practice medicine in London while pursuing other studies at Emmanuel College, Cambridge. He established his own medical practice in London in 1799. In 1801 he was appointed professor of physics at the Royal Institution but resigned the position 2 years later in favor of his medical practice and independent scholarly pursuits. He was appointed in 1804 as foreign secretary of the Royal Society, a position he held until his death on May 10, 1829.

Young's contributions to the sciences are many: the Young-Helmholtz theory of color perception, the Young modulus (a mathematical constant), experiments supporting the wave theory of light, and studies of vision, time, longitude, properties of liquids, environmental hazards, acoustics, tides, botany, zoology, astronomy, energy, climatology, and even life insurance. During vacations, he sought to unlock the mystery of the Rosetta Stone.

A papyrus owned by a friend drew Young's attention to the Egyptian script, and in 1814 he set about deciphering the stone. Comparing the undeciphered enchorial (demotic) script with the Greek version, Young compiled a list of word equivalents. He discovered or confirmed (again, accounts differ) that cursive demotic was derived from hieroglyphic. Positing that hieroglyphic symbols were used phonetically in transcribing foreign names, he deciphered the names of Ptolemy and his queen Berenice as well as a few common words. He failed to carry this insight as far as he might have, however, maintaining instead the long-standing assumption that the majority of hieroglyphic signs were nonalphabetic. Still, he correctly assigned phonetic values to at least five demotic signs and correctly isolated a number of hieroglyphic word groups, a considerable achievement.

The extent of Young's contribution to deciphering hieroglyphics is muddied by a personal, professional and national rivalry with Jean-François Champollion, who in 1814 asked Young for a cast of the Rosetta Stone. Relying (how heavily is a matter of debate) on Young's findings and insights of his own, Champollion was able to decipher the hieroglyphic script that had eluded Young. While the exact nature of each scholar's contribution to unlocking the stone may be debatable, Young clearly eased the way for Champollion and may be credited with deciphering the alphabetic demotic script.

Yue Languages *See:* Chinese.

Yukaghir

G D S Anderson, Max Planck Institute, Leipzig, Germany, and University of Oregon, Eugene, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

Yukaghir is not a single language, but is actually a small language family consisting of two nearly extinct languages of northeastern Siberia, i.e., Tundra (Northern Yukaghir; *Ethnologue* code YKG) and Kolyma (Southern Yukaghir; *Ethnologue* code YUX). (http://www.ethnologue.com). The speakers of these languages and the languages themselves are known by the self-designations of *Wadul* (Tundra) and *Odul* (Kolyma). Fewer than 200 total speakers, possibly as few as 40, live in northeastern Siberia. Conventionally labeled as language isolates, some consider Tundra and Kolyma to be distant relatives of the Uralic languages. The Yukaghiric family probably originally included two now extinct languages, Chuvan and Omok.

Yukaghiric-speaking peoples were once dominant over a vast area in northeastern Siberia, practicing reindeer husbandry and subsistence hunting and fishing. Yukaghiric-speaking peoples at first assimilated Tungusic-speaking peoples culturally, but eventually the Even (Tungusic) people assimilated the Yukaghiric people linguistically, and now include a discernible Yukaghiric substrate. The Tundra Yukaghir language is spoken in two villages, Andryushkino and Kolymskoe. Kolyma Yukaghir is found predominantly in the village of Nelemnoe. Both Yukaghir languages are moribund, spoken now only by a few elders. The Yukaghir people have shifted mainly to speaking Russian, but in Andryushkino village they are mostly shifting to Yakut (Sakha), a locally dominant Turkic language.

Yukaghir possesses a range of contrastively palatalized segments in the consonant system, a pattern commonly found throughout the Siberian area. Unlike most northern and Siberian languages, Yukaghir is like Yakut in not permitting *ŋ*-in word-initial position. However, the common four-way place contrast for nasals (*m/n/ñ/ŋ*) seen across the languages of Siberia is an old and stable feature in Yukaghir, going back at least to the Proto-Yukaghir(ic) stage (Anderson 2003). Example (1) shows word forms in Tundra, Kolyma, and Proto-Yukaghir (from Krejnovich, 1958, 1982: 13–14):

(1)

Tundra	**Kolyma**	**Proto-Yukaghir**	**Gloss**
nonol	nonol	*nonol	'loop, noose'
amun	amun	*amun	'bone'
ñaʁa	ñaʁa	*ñaʁa	'together'
aŋa-ŋ	aŋa	*aŋa	'mouth'

Like most other Siberian languages, Yukaghir makes use of a range of case forms of nouns. This includes both areally common and typologically unusual formations. To the areally common group of features belong the opposition of instrumental (INSTR) case forms (Example (2a); Krejnovich, 1982: 49–50)) and comitative (COM) case forms (Examples (2b) and (2c); Krejnovich 1982: 45, 46)):

(2a)

Tundra Yukaghir	**Kolyma Yukaghir**
-lek, -leŋ	-le, -lek
s͡a-lek pajduk	čoɣoye-le
'hit with a stick'	'with a knife'

In Examples (2b) and (2c), comitative denotes possession as well, and conjoins two nouns (PV, preverb):

(2b) **Kolyma Yukaghir**
núme-ñej
dwelling-COMIT
'with a dwelling,' 'he has a dwelling'

(2c) **Tundra Yukaghir**

ile-ñej	ila:me	me-qaldej-ŋi
reindeer-COMIT	dog	PV-run.off-3PL

'the dog ran off with the reindeer,' 'the dog and the reindeer ran off'

To the unusual group of case features belongs the characteristically Yukaghir but typologically unusual system of 'focus' marking. Simplifying matters somewhat, this system is as follows: there is (1) an unmarked form that encodes speech act participants and lexical nouns in agent-focus and agent/subject-topic functions; (2) a marked 'neutral' case used with nonlocutor agent/subject topics, object-topics with locutor agents, and forms that lack the focus case (nonlocutor personal pronouns, proper names, etc.); and (3) the 'focus' case that encodes subject or object focus. Noun phrases (NPs) marked with focus frequently reference indefinite NPs, and focus-case marking often serves to introduce participants into

the discourse (see Maslova (2003a: 51ff) for further details).

In terms of the clausal syntax of simple and complex sentences, Yukaghir is similar to many other indigenous Siberian languages. The language shows dominant subject-object-verb constituent order and uses a wide range of adverbial 'converb' forms in subordinate clause formation, as well as the characteristic system of case-marked nominalized verbs to mark a wide range of functional subtypes of subordinate clauses, as shown in Example (3a) (the first two words are from Krejnovich (1958: 198) and Fortescue (1988: 41), respectively; the original source for the third word is unknown) and Example (3b) (from Maslova (2003b: 372)) (abbreviations: NOM, nominal; LOC, locative; POSS, possessive; PL, plural; NF, nonfinite; NEG, negation; PROHIB, prohibitive; ACC, accusative; DESID, desiderative; INTRANS, intransitive):

(3a) **Yukaghir**

u:r-eŋ	u:-l-rane	u:-l-lek
go:ACTION.NOM-LOC	go-ACTION.NOM-LOC.II	go-ACTION.NOM-INS
'when (I) went'	when he went'	'after going'

(3b) **Kolyma Yukaghir**

qa:qa:-pe-gi	ajli-de-ge
grandfather-PL-POSS	forbid-3.NF-LOC
"el+qon-ŋi-lek"	mon-de-ge
NEG-go-PL-PROHIB	say-3.NF-LOC
tamun-gele	uørpe-p-ki
that-ACC	child-PL-POSS
el+med-o:l-ŋi	
NEG-listen-DESID-3pl.intrans	

'Their grandfather forbids (it), saying "don't go" but the children do not obey'.

Z

Zabrocki, Ludwik (1907–1977)

Z Wąsik, Adam Mickiewicz University, Poznań, Poland

© 2006 Elsevier Ltd. All rights reserved.

Ludwik Zabrocki was born in Czersk (at that time Germany) on November 24, 1907, into a family of Pomeranian peasants, and died in Poznań (Poland) on October 8, 1977, as Professor in Linguistics at Adam Mickiewicz University. After finishing his junior high school in Chojnice, he went to the University of Poznań, where he studied between 1927 and 1931 Polish, German, and Indo-European under the guidance of, among others, H. Ulaszyn and M. Rudnicki. His M.A. thesis, devoted to 'The dialect of Tuchola Forests' (*Gwara Borów Tucholskich*), was published in 1934. After World War II he continued his academic career at the University of Poznań with a Ph.D. in 1945 and a D.Litt. in 1949. At that time (1946) he acted, *inter alia*, as a member of the governmental commission for establishing the names of localities in the so-called Regained Territories in West and North of Poland. In 1953, he was appointed to the Chair of Germanic Languages, and subsequently, in 1964, gave birth to an autonomous Section of Applied Linguistics (dissolved in 1968), the second of its kind in the world, and which gave rise to the later Institute of Linguistics.

In 1968/1969, Ludwik Zabrocki's name appeared among the presidents of the Societas Linguistica Europaea: after André Martinet (1966/1967) and Björn Collinder (1967/1968). In 1969, he created the Polish Neo-philological Association and became its first president. For his outstanding achievements he was offered the membership of the Polish Academy of Sciences in 1971. He was also the co-founder and editor of three international journals, *Lingua Posnaniensis*, *Biuletyn Fonograficzny*, and *Glottodidactica*. In 1973, he organized the Institute of Linguistics, which he directed until his death. With his scientific publications he contributed to the field of comparative linguistics, working in the domains of Germanic, Indo-European, and Finno-Ugric languages and phonetics, as well as Slavonic and Polish dialectology, entering also the fields of the theory of language and the methodology of foreign language teaching with special reference to confrontative and contrastive applied linguistics. His principal monographs refer to the topics: 'Fortition and lenition in Indo-European and Finno-Ugric languages' (*Usilnienie i lenicja w językach indoeuropejskich i ugrofińskim*, 1951), 'Communicative communities in the genesis and development of the German language' (*Wspólnoty komunikatywne w genezie i rozwoju języka niemieckiego*, 1963), 'Linguistic foundations of the teaching of foreign languages' (*Językoznawcze podstawy metodyki nauczania języków obcych*, 1966), and 'Cybernetic models of language communication' (*Kybernetische Modelle der sprachlichen Kommunikation*, 1975). The output of his scientific activity has been published by the Foundation of Language Structure and Development (*U podstaw struktury języka*, 1980).

Zambia: Language Situation

N C Kula, University of Leiden, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Zambia is a country in southern central Africa, with an area of 752 614 km^2 and a population of 10 307 333, based on a July 2003 estimate. It borders the Democratic Republic of the Congo (DRC) to the north, Tanzania, Malawi, and Mozambique to the east, Zimbabwe and Botswana to the south, and Namibia and Angola to the west.

There are up to 80 tribes in Zambia, which are usually used synonymously to reflect the number of languages spoken. In this multitribal context the differentiation of languages and dialects is an arduous one that involves not only linguistic factors and geographic location but also the maintenance of ethnic and cultural differences. The majority of the Bantu-speaking peoples of Zambia, particularly in the north, east and west, migrated from the Luba-Lunda empires of the upper Congo basin (now the DRC). Those not from the DRC came from East Africa into eastern Zambia (the Mambwe, Inamwanga, and Tumbuka) or from the south into eastern Zambia (the Ngoni). These migrations date from the 16th century and created the settlements that make the present-day tribes.

Kashoki (1978) identified up to 17 groups based on general linguistic closeness, reflected in similar phonology and overlapping vocabulary. The groups are divided further into clusters that can be considered to be dialects of the same language. Thirteen of these groups, given in Table 1, can be considered significant. 'Location' in the table refers to the geographically located provinces of Zambia. The Copperbelt Province (CB) lies above the Central Province and to the right of the Northwestern Province.

Based on this clustering, we can say there are about 25 distinct languages spoken in Zambia although there is some mutual comprehension between clusters within the same group as opposed to between groups. This clustering has resulted from different leveling processes such as intermarriage, loss of original group identities, geographical proximity, political domination, and mutual trade. Thus, for example, although the Ngoni on arrival in Zambia spoke a Nguni or Zulu language, they now speak the language of the people they conquered and among whom they married, the Nsenga, Tumbuka, and Chewa. The Ngoni are today divided between the Tumbuka of Chief Magodi and the Nsenga of Chief Mpezeni but it is popularly thought in Zambia that all Nyanja-speaking peoples are Ngoni, so that the Chewa, Nsenga, and others normally resident in the Eastern Province are referred to collectively as 'Ngoni.' The close relation of the Bantu languages of Zambia is also reflected in Guthrie's (1948) classification, where they fall into the adjacent K, L, M, and N zones.

Fortune (1970) also reported small, scattered nomadic groups of the Goba (also called Gowa, Gova, or Korekore) in the Southern Province and the Hukwe and Kengo on the fringes of the Western Province as the only instance of speakers of click/Khoisan languages that appear not to have been enumerated in the 1969 census.

In addition to indigenous Zambian languages, there are languages of European and Asian descent spoken, of which English is the main one. There are other African languages spoken, of which the most

Table 1 Language groups and dialect clusters of Zambia

Group	*Location*	*Dialect clusters*
A	Northern	[Aushi, Chishinga, Kabende, Mukulu, Ngumbo, Twa, Unga, Bemba, Bwile, Luunda (Lunda), Shila, Tabwa (Taabwa)]

	Central	[Lenje, Twa]
	Central	[Soli]
L	Eastern	[Tumbuka, Fungwe, Senga, Yombe, Ngoni (of Chief Magodi speak Tumbuka)]

notable is Swahili, which has small settlements of speakers in the Copperbelt and northern provinces.

English is the most important official language, used for the administration of the country, in parliament, as a medium of instruction in schools, and for all national and international official communication. The use of English as an official language has its historical origins from its use under British colonial rule. Apart from English, there are seven Zambian languages that have official status. The languages chosen are those with the largest number of native or mother tongue speakers. Thus, according to the 1969 census: Bemba (18.6%), Nyanja (11.3%), Tonga (10.7%), Lozi (5.6%), Kaonde (2.9%), Lunda (2.5%), and Luvale (2.4%). Apart from number of speakers, geographic spread is also taken into consideration so that the northern (Bemba), southern (Tonga), eastern (Nyanja), western (Lozi), central (Nyanja) and northwestern (Kaonde, Luvale, Lunda) parts of the country are represented. This also correlates to the biggest language in distinct language groups. Thus the northwest inputs three languages which are spoken to more or less the same extent because they belong to different language groups.

The seven official Zambian languages are used for literacy campaigns, radio broadcasting, dissemination of official government information, political statements, and in courts of law. More recently they have also been used in news broadcasts on TV, as well as in light entertainment programs. Although the Ministry of Education has in various policy documents (1992, 1996) recommended that all pupils be given the opportunity to learn initial basic skills of reading and writing in one of the seven official Zambian languages, English predominantly remains the main medium of instruction and certainly the only one above the fifth grade, from which point the Zambian languages are offered as subjects. The seven official Zambian languages also have fortnightly newspapers but here again English is the only official language that enjoys at least three daily papers (the *Times of Zambia*, the *Daily Mail* and the *Post*), not to mention other weekly ones.

It can in general be said that the seven official Zambian languages are lingua francas in different regions of the country. The 1978 survey of Kashoki and Ohannessian showed that Bemba and Nyanja, followed by Tonga and Lozi and to a lesser degree Luvale, Kaonde, and Lunda, function as vehicles of wider communication in the country. In addition to their larger number of native speakers, this also seems to follow from their official status, which increases their number of second-language speakers. Thus, 56.2% of the total population are recorded as speakers of Bemba, 42.1% of Nyanja, 26.1% of English, and 23.2% of Tonga (Kashoki, 1978). If only rural Zambia is considered the figures reduce to 46%, 36.6%, 19%, and 24.2% respectively and increase in urban Zambia to 83.8%, 57.2%, 45.3%, and 20.6% respectively. Thus, while English remains the most important official language, Bemba and Nyanja are spoken and understood more widely. The figures here must, however, be adjusted to perhaps reflect a higher percentage of English given the rising education levels since 1978.

A consequence of having many different languages and the promotion of official languages is the development of multilingualism in the country. On average, 2.5 languages excluding English are spoken per person. The problem is of course that what is referred to as a different language in this context, particularly if it is within the same language group, is far from clear.

The only language survey on Zambia is Ohannessian and Kashoki (1978). It is feared that some languages reported on here but not enumerated in the 1969 and 1990 censuses, particularly in the Western Province (e.g., Nyiha, Lambya [Lamba], Wandya) may be severely endangered. However, a comprehensive survey of the current language situation still remains to be carried out.

Zampolli, Antonio (1937–2003)

I Mani, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

The computational linguist Antonio Zampolli, born in 1937, began his career as a student of Father Roberto Busa, who had been working in Gallarte, Italy, on a text concordance and index to the works of Thomas Aquinas, the *Index Thomisticus*. The application of computing technology for research in the humanities remained a fundamental concern throughout Zampolli's research career. His early papers from the late 1960s investigated statistical analyses of text and the development of electronic dictionaries. A paper from 1968, for example, dealt with 'Statistical analysis of the phonological composition of Italian, conducted with an IBM system.' Over time, his interests grew to cover a wide range of topics: his publications, numbering more than 250, addressed problems in corpus linguistics, mathematical linguistics, digital libraries, computational lexicography, standards for data sharing, machine translation, formal grammars and parsers, and computer-assisted language learning, among others.

Zampolli became a full professor of mathematical linguistics at the University of Pisa in Italy in 1977. Shortly thereafter, he established the Institute for Computational Linguistics of the National Research Council in Pisa, which grew under his directorship into a major center for natural language processing. Zampolli was skilled as a bridge-builder between disciplines, and he was a key figure in achieving cooperation and standardization in language resources, coordinating several well-known European and Italian projects in these areas. He was successful in establishing international collaboration and the building up of a large-scale infrastructure for computational linguistics research and language processing technology.

Zampolli was instrumental in the founding of the *Association for Literary and Linguistic Computing* in 1973, and was also a founder and president of the *European Language Resources Association* (ELRA), created in 1995 to focus on collection and distribution of language resources. He played a key role in instituting the *Text Encoding Initiative*. He was behind the creation of the *International Conference on Language Resources and Evaluation* (LREC) and also directed the *Pisa International Summer School for Literary and Linguistic Computing*.

Zampolli was appointed to the executive committees of numerous associations and delegations, including the *Association for Computational Linguistics*. He served on the Advisory Board of the Linguistic Data Consortium, as well as on the Editorial Board of *Computers and the Humanities,* and the *Journal of Applied Linguistics*, among others. He also co-edited the influential *Survey of the State of the Art in Human Language Technology* (Cambridge, 1997). He also coordinated the *Expert Advisory Group on Language Engineering Standards* (EAGLES), an initiative of the European Commission, aimed at accelerating the development of standards for large-scale linguistic resources, and their exploitation and evaluation, and the successor project *International Standards for Language Engineering* (ISLE).

Antonio Zampolli died in 2003 in a fire at his home in Pisa. The ELRA board has created a prize in his memory, awarded every two years, the first one being given in 2004 to Professor Frederick Jelinek of Johns Hopkins University in Baltimore, USA.

Zapotecan

G A Broadwell, State University of New York, Albany, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Zapotecan languages belong to the Otomanguean family and are spoken across a large portion of Oaxaca, Mexico. Zapotecan is divided into two branches – Chatino and Zapotec proper. The number of languages in each group is controversial, but the Summer Institute of Linguistics recognizes 6 Chatino languages and 58 Zapotec languages.

Zapotec languages are spoken by over 200 000 people located over much of the eastern half of Oaxaca. Varieties of Zapotec divide broadly into three groups. The Valley-Isthmus group includes most varieties spoken in the valley of Oaxaca, extending to the Isthmus of Tehuantepec. The Northern group is spoken in the mountains to the north of the Valley of Oaxaca, and the Southern group is spoken in the mountains to the south. All three groups are quite diverse and contain many distinct languages.

Chatino languages are spoken in a smaller mountainous area in southwestern Oaxaca by perhaps 30 000 people.

The earliest documentation of Zapotecan languages comes from grammars, dictionaries, and religious material from the Spanish colonial period. Archaeological sites associated with the Zapotec state of ca. 100 B.C. to ca. 900 A.D. also contain Zapotec hieroglyphic writing. Efforts to decipher Zapotec hieroglyphics are still ongoing.

Phonological Characteristics

In Zapotec languages, most consonants are divisible into two morphophonologically defined groups called 'fortis' and 'lenis.' For stops and fricatives, fortis is largely equivalent to voiceless and lenis to voiced. However, the fortis/lenis distinction is also found in the nasals and sonorants, where the phonetic realization of fortis is not voicelessness, but some other characteristic that generally includes longer duration.

The morphological examples in (2) below from Mitla Zapotec show that long sonorants and voiceless obstruents seem to form a natural class. Many analyses of Zapotec historical phonology also analyze fortis consonants as having originated from geminates and consonant clusters.

Many Zapotec languages, especially those in Valley group, show contrastive phonation type differences. San Dionicio Ocotepec Zapotec, for example, shows a distinction between modal, breathy, creaky, and checked vowels. Consider the following minimal and near-minimal pairs:

(1) San Dionicio Ocotepec Zapotec

[bz̤̀l]	'flame'	(breathy)
[bẑ̰l]	'meat'	(creaky)
[bá:ld]	'how many'	(modal)
[bẑ̤l]	'bullet'	(breathy)
[bẑ̰ld]	'fish'	(breathy)
[bɛ̌ʔld]	'snake'	(checked)

All Zapotecan languages are tonal. The number of reported tones varies from two tonal levels to four, with a variety of contour tones. The largest number of tonal contrasts in the family appears to be Zoogocho Zapotec, which is reported to have four tone levels and seven contours, for a total of 11 tonal contrasts.

Morphological Characteristics

Zapotec languages do not have a passive, but generally show morphological relationships between pairs of verbs that differ in valence. In one typical pattern, an intransitive stative verb begins with a lenis consonant, while the corresponding transitive active verb begins with the corresponding fortis consonant. Consider the following examples from Mitla Zapotec:

(2) Mitla Zapotec

[zæb]	'to sink (intr.)'	[sæb]	'to sink (tr.)'
[dẹb]	'to be wrapped'	[tẹb]	'to wrap'
[nz̤̈t]	'to be lost'	[nnz̤̈t]	'to lose'
[lib]	'to be tied'	[llib]	'to tie'

There are generally also other such pairs that show less regular correspondences.

Zapotec verbs are inflected with aspectual prefixes. The number of aspects varies from language to language. In Zoogocho Zapotec, for example, there are continuative, stative, completive, potential, and dubitative aspects. San Lucas Quiaviní Zapotec has progressive, habitual, perfective, irrealis, subjunctive, neutral, and definite (future) aspects.

Zapotec verbs do not show agreement, though pronominal subjects (and some pronominal objects) cliticize to the verb. Consider the following examples from San Dionicio Ocotepec Zapotec:

(3) San Dionicio Ocotepec Zapotec

(3a) Ù-dàw réé = bííny bzyàá.
COM-eat PLUR = person bean
'The people ate beans.'

(3b) Ù-dàw = réby bzyàá.
COM-eat = 3.HUMAN.PLUR bean
'They ate beans.'

(3c) Ù-dàw = réby = rèny
COM-eat = 3.HUMAN.PLUR = 3.INAM.PLUR
'They ate them.'

Zapotec languages often show a large number of third-person pronominal categories. For example, San Lucas Quiaviní Zapotec distinguishes between proximal (near) and distal (far) third persons, as well as between animal, respectful, formal, and reverential third-person categories. These categories are not morphologically marked on nouns themselves, but on independent or clitic pronouns that are coreferential with the nouns. Pronominal category is also not completely fixed, but may vary somewhat according to a speaker's point of view and according to the structure of the narrative.

Syntactic Characteristics

Zapotecan languages show head-inital order in phrases. Clauses are VSO, noun phrases are N-initial, and the language is prepositional. The following examples from San Dionicio Ocotepec Zapotec and Yaitepec Chatino show these properties:

(4) San Dionicio Ocotepec Zapotec
Ù-dèèdy Gùstáàb ʃ-kèès Màríì lòò Móòny
COM-give Gustavo POSS-pot Maria to Ramón
'Gustavo gave Maria's pot to Ramón.'

(5) Yaitepec Chatino (Pride, 1965: 82)
Nʃiʔyu^{32} neʔ^{3} yka^{3} loʔo^{1} taʔa^{23} loʔo^{1}
cutting he wood with brother with
siyera^{4} ka^{3} sĩ^{2} bra^{3}kõʔ^{2}.
saw yesterday evening then
'He was cutting wood with his brother with a saw yesterday evening then.'

Though the languages are verb-initial, there is generally an elaborated hierarchy of positions to the left of the verb. These frequently include special positions for topical, focal, negative, and interrogative phrases. The following examples from Quiegolani Zapotec illustrate several of these positions:

(6) Quiegolani Zapotec
[Tʂu]$_{\text{Interrog}}$ [men]$_{\text{Neg}}$ wii-tʔ
who nothing saw-NEG
'Who saw nothing?'

(7) Quiegolani Zapotec
[Laad ʂ-unaa dolf]$_{\text{Focus}}$ ʤe
FOC POSS-wife Rodolfo already
z-u nga.
PROG-stand there
'Rodolfo's wife was already standing there.'

All the Zapotecan languages also appear to show the phenomenon known as 'pied-piping with inversion.' When a subpart of NP or PP (and sometimes other constituents) is questioned, the entire phrase moves to the clause-initial interrogative position, but shows an inverted order, in which the interrogative precedes the head of the phrase:

(8) San Dionicio Ocotepec Zapotec
[Túú lòò]$_{\text{Interrog}}$ ù-dèèdy Gùstáàb gèès?
who to COM-give Gustavo pot
'Who did Gustavo give the pot to?'

In broad syntactic terms, Zapotecan languages generally conform to the areal features of other Mesoamerican language families such as Mayan, Mixe-Zoquean, and Totonacan. Zapotecan languages differ from these other groups in lacking agreement and voice morphology and having a more rigid word order.

Conclusion

All Zapotecan languages are endangered, and in some communities, only a few elders speak the language. In other communities, the language is spoken by a much larger proportion of the population, but there are still economic pressures that favor language shift to Spanish or emigration to the United States and other parts of Mexico. These factors make language preservation and documentation work an urgent priority.

Zarncke, Friedrich (1825–1891)

K R Jankowsky, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Friedrich Zarncke was born on July 7, 1825, in Zahrenstorf (Mecklenburg), Germany. After graduation from high school in 1844, he attended the University of Rostock to study philology and, for one semester, theology. A year later, he relocated to Leipzig, where the Classicist Gottfried Hermann (1772–1848) and the Germanist Moriz Haupt (1808–1874) became his principal teachers. Following a one-semester stay in Berlin, he returned to Rostock, obtaining his doctorate in 1847 solely by an oral *examen rigorosum* in German, English, and Greek, which he passed with distinction. Subsequently, he worked for 3 years in a private library cataloguing literary source material of the late Middle Ages. This activity laid the foundation for his lifelong preoccupation with textual criticism of older and more recent texts. In 1850, he accepted editorship of the newly established *Literarisches Centralblatt*, a weekly publication surveying important works in *Germanistik*. Zarncke remained editor until his death, devoting most of his time to this monumental work of far-reaching consequence for the development of his field.

Zarncke began his teaching career at Leipzig University in 1854 and 4 years later succeeded Moriz Haupt as professor of German language and literature. He never left Leipzig again and served the university as an able administrator, an inspiring teacher, and a prolific scholar of extensive influence. He was elected university president three times, which was quite unusual at that time. The large number of his students include such prestigious names as Wilhelm Braune (1850–1926), Hermann Paul (1846–1921), and Eduard Sievers (1850–1932), who acknowledged their indebtedness to him as an extraordinarily effective teacher.

Apart from his skillful editorial work in the *Centralblatt* and numerous book editions, such as Brant's *Narrenschiff*, Zarncke also distinguished himself with critical studies such as the *Nibelungenlied* and a number of publications that combined his equally strong interests in literary and linguistic studies. His greater emphasis on literary research in later years (e.g., his treatises on Goethe and Reuter) have to be viewed likewise within the context of his conviction that literary and linguistic pursuits are inseparably interrelated.

Zemskaja, E. A. (b. 1926)

L P Krysin, Russian Academy of Sciences, Moscow, Russia

© 2006 Elsevier Ltd. All rights reserved.

Elena A. Zemskaya (born November 5, 1926) is a well-known Russian philologist and expert in Russian and Russian literature. Her father was A. M. Zemsky, the noted linguist, teacher, and author of textbooks of the Russian language. Her mother was the sister of the famous writer Mikhail Bulgakov.

Zemskaya is a graduate of the philology faculty of Moscow State University. Her teachers were such outstanding scholars as V. V. Vinogradov and M. N. Peterson. Quite soon after graduating from the university she found herself as a specialist in Russian word formation. Her books in this field, *Sovremennyi russkii yazyk. Slovoobrazovaniye* (1973) (Modern Russian. Word formation), *Slovoobrazovaniye kak deyatelnost* (1992) (Word formation as an activity), the book popularizing the subject, *Kak delayutsya slova* (1963) (How words are formed), as well as numerous articles, have a well-deserved reputation among specialists. No one writing on the subject can disregard Zemskaya's works. Teaching this subject at universities is also unthinkable without taking her works into account.

Another field of Zemskaya's expertise is Russian colloquial language. She guided and contributed to a number of works: *Russkaya razgovornaya rech* (1973) (Russian colloquial language), *Russkaya razgovornaya rech. Teksty* (1978) (Russian colloquial language. Texts), *Russkaya razgovornaya rech. Obshchiye voprosy. Slovoobrazovaniye. Sintaksis* (1981) (Russian colloquial language. General questions, word-formation, syntax), *Russkaya razgovornaya rech. Fonetika. Morfologiya. Leksika. Zhest* (1983) (Russian colloquial language. Phonetics, Morphology, Lexis, Gesture). She wrote the textbook *Russkaya razgovornaya rech: lingvisticheskii analiz i problemy obucheniya* (Russian colloquial language: linguistic analysis and problems of teaching) (1979, 1987, 2004). Some of Zemskaya's works studying other varieties of the Russian national language are connected with those on Russian colloquial language. She edited such books as *Gorodskoye prostorechiye: problemy izucheniya* (1984) (Urban popular language: problems of study), *Raznovidnosti gorodskoi ustnoi rechi* (1988) (Varieties of urban oral speech). In 1999 *Tolkovyi slovar russkogo obshchego zhargona* (An explanatory dictionary of Russian general slang) was co-authored by Zemskaya with O. P. Yermakova and R. I. Rozina. Active processes in Russian at the end of the 20th century are examined in the book *Russkii yazyk kontsa XX stoletiya* (1996) (Russian at the end of the 20th century) written by a few authors under Zemskaya's guidance. In co-authorship with M. V. Kitaigorodskaya and N. N. Rozanova, Zemskaya published one of the first works in Russian philology devoted to gender distinctions in the language and communicative behavior of people (1993).

The functioning of Russian abroad is also one of the issues she has addressed. She wrote some articles about this subject, as well as the book *Yazyk russkogo zarubezhya* (2001) (The Russian language abroad) in co-authorship with M. J. Glovinskaya and M. Bobrik, in which these scholars describe some speech peculiarities of Russian emigrants living in Europe and the United States.

A particular field of Zemskaya's work is the study of M. Bulgakov's biography and the history of his family. In 2004, she published the book *Mikhail Bulgakov i yego rodnye. Semeinyi portret* (Mikhail Bulgakov and his relatives. Family picture) containing some unique documents, letters, and photographs.

From the beginning of the 1950s to now she has worked at the Vinogradov's Institute of the Russian Language of the Russian Academy of Sciences.

Zemskaya always scrutinizes topical phenomena and processes typical of Russian. Proceeding from the thesis put forward by M.V. Panov at the beginning of the 1960s, that Russian colloquial language is self-sufficient (as a particular subsystem of the standard language), she considerably developed the thesis with her own theoretical investigations and by the analysis of numerous facts gathered as a result of many records of spontaneous oral speech. In the course of these investigations a method of getting information about living oral speech was worked out. Later on it was used by other scholars who studied oral forms of languages.

Studying different processes in modern Russian, Zemskaya deliberately rejects a purely normative approach to new phenomena. She is right to believe that the normative estimation of any novelty in the sphere of lexis, word-formation, or grammar should be preceded by a thorough and unprejudiced study of the nature of new phenomena and causes of their appearance in the language.

Zeuss, Johann Kaspar (1806–1856)

R Schmitt, Laboe, Germany

© 2006 Elsevier Ltd. All rights reserved.

Johann Kaspar Zeuss, the founder of Celtic philology, was born in Vogtendorf (near Kronach in Franconia) on July 22, 1806, and took up philology and history on a large scale at the University of Munich in 1826. He passed the teacher's examination in 1830 and beginning in 1832 taught Hebrew at a Munich grammar school. After obtaining his doctorate in 1838 at the University of Erlangen, he was appointed in the next year professor of history at the Lyzeum (college of education) in Speyer. In 1847, in recognition of his first masterly publications, Zeuss was appointed to a chair of history at the University of Munich, but after a few months he gave it up in exchange for a professorship at the Lyzeum in Bamberg. From his youth, he lived for his studies a life of privation. He died at age 50 on November 10, 1856, in his native village.

Zeuss became famous overnight for his grand first work, *Die Deutschen und die Nachbarstämme* (1837), which deals with the origin and the spread of the ancient Central European peoples according to both historical records and linguistic evidence and thus by constructive criticism of these sources became a masterpiece of joining together linguistics and history. The book is of some relevance today owing to the analyses of the ethnonyms in question. In this context belong likewise a small book on the origin of the Bavarians (1839) and the (hand-written) thesis of 1838 about *Germania* in Chapter II 11 of Ptolemy's *Geography* (published in facsimile by Hablitzel, 1987: appendix 11; transcribed and translated in Forssman, 1989: 167–219).

Apart from historical studies and the edition of two collective codexes of medieval documents, which led him also to preliminary data collection for an Upper German onomasticon, Zeuss, in his efforts to precisely distinguish Germanic ethnonyms and geographical names from Celtic linguistic and onomastic materials, turned increasingly more to Celtic studies. He collected the oldest Celtic sources mostly from the relevant manuscripts, particularly those (as completely as possible) in the Old Irish and Old Welsh languages (e.g., the Würzburg and Milan glosses); took into account the scattered Gaulish evidence; and, based on careful philological study and astute analysis, described the grammar of all then known ancient Celtic languages and compared them with one another in his

Apart from historical studies and the edition of two collective codexes of medieval documents, which led him also to preliminary data collection for an Upper German onomasticon, Zeuss, in his efforts to precisely distinguish Germanic ethnonyms and geographical names from Celtic linguistic and onomastic materials, turned increasingly more to Celtic studies. He collected the oldest Celtic sources mostly from the relevant manuscripts, particularly those (as completely as possible) in the Old Irish and Old Welsh languages (e.g., the Würzburg and Milan glosses); took into account the scattered Gaulish evidence; and, based on careful philological study and astute analysis, described the grammar of all then known ancient Celtic languages and compared them with one another in his

epoch-making 1200-page *Grammatica Celtica* (1853). This great book was a pioneering work of the same kind as Jacob Grimm's *Deutsche Grammatik* (1819–1837) had been for the Germanic languages. It is worthy of admiration all the more because Zeuss had acquired those languages by self-study and could rely on nothing other than a grammar of Modern Irish.

Ziegenbalg, Bartholomaeus (1682–1719)

J-L Chevillard, CNRS, Université Paris 7, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Bartholomaeus Ziegenbalg, a German born in Pulsnitz, is, among Lutheran missionaries, the pioneer of Tamil studies. His name is linked to two places: Tranquebar, where he arrived in 1706, sent by the King of Denmark, Frederick IV, along with Henry Plutschau, and Halle (Saale), where a number of documents he and others sent from Tamil Nadu are kept in the August Hermann Francke Foundation archives. After his arrival, Ziegenbalg started to learn Tamil and set about compiling Tamil–German word lists. After 2 years, he had a list of 20 000 words, which Ziegenbalg claimed was based on a reading of 200 authors (Singh, 1999: 70), and another list of 17 000 words useful for reading poetry, which seems to have been an adaptation of a traditional poetical Tamil lexicon, possibly the *Cūṭāmaṇi Nikaṇṭu* (Jeyaraj, 1996). Unfortunately, due to Ziegenbalg's untimely death, his Tamil–German dictionary was never published, but it served, through a Latin translation (James, 2000: 151), as the basis for the work of his followers, notably Johann Philipp Fabricius's 1786 English–Tamil dictionary (James, 2000: 157). The other important linguistic activity of Ziegenbalg was the writing of a Tamil grammar in Latin, the *Grammatica Damulica* (1716/1985). He is also known for his work on Indian religion and for his Tamil translation of the New Testament. To this must be added his contribution to the archives in Halle.

Unfortunately, due to Ziegenbalg's untimely death, his Tamil–German dictionary was never published, but it served, through a Latin translation (James, 2000: 151), as the basis for the work of his followers, notably Johann Philipp Fabricius's 1786 English–Tamil dictionary (James, 2000: 157). The other important linguistic activity of Ziegenbalg was the writing of a Tamil grammar in Latin, the *Grammatica Damulica* (1716/1985). He is also known for his work on Indian religion and for his Tamil translation of the New Testament. To this must be added his contribution to the archives in Halle.

Zimbabwe: Language Situation

H Chimhundu, University of Zimbabwe, Harare, Zimbabwe

© 2006 Elsevier Ltd. All rights reserved.

Languages Spoken

There are 16 African languages that are spoken in Zimbabwe (Hachipola, 1996: 1–6). All of them belong to the Bantu family except one, Tshwawo, which is Khoisan. The 15 Bantu languages are Shona, Ndebele, Kalanga, Chewa (Nyanja), Tonga (of Mudzi district), Tonga (cp. Zambia), Nambya, Shangani, Barwe, Sotho (Fengu), Venda, Chikunda (Kunda), Xhosa, Hwesa, and Sena. The two clearly dominant indigenous languages are Shona, spoken by more than 75%, and Ndebele spoken by up to 16%, of the estimated population of 13 million. Both are sometimes referred to as national languages, but that status is only nominal. English, which is the mother tongue of not more than 100 000 people now, is still firmly entrenched as the language of government, business, the media, education, training, and specialized information, as well as upward social mobility and wider communication within and outside Zimbabwe's borders.

As far as the sizes of the speech communities are concerned, Zimbabwe's language situation is less complex than those that obtain elsewhere in Africa, because the two national languages are clearly dominant in their respective areas, where they are also the languages taught in schools and used for limited administrative and judicial functions. Ndebele is dominant in the three western provinces of Matebeleland North, Bulawayo, and Matebeleland South. Shona is dominant in all the other seven provinces of Midlands, Masvingo, Manicaland, Mashonaland East, Harare, Mashonaland North, and Mashonaland West. What this means is that some Shona speakers and Ndebele speakers are not ethnic Shona or ethnic Ndebele. In fact, within the predominantly Ndebele-speaking area, the ethnic Ndebele are actually a minority. The reasons for this are historical and date back to the Umfecane or Nguni dispersal, when various Nguni groups fled from Shaka, the Zulu king. In Malcolm Guthrie's classification, Ndebele is in Zone 40, Group S, along with Zulu, Xhosa, and Swati.

Shona is also in the Southern Bantu group, where it is classified in Zone 10, Group S. The language is a cluster of six dialects, namely Manyika and Ndau in the east, Karanga in the south and midland areas, Kalanga in the west, Zezuru in the central and northern areas, and Korekore in the northeastern area. However, Kalanga has been separated from the rest of Shona for a long time; the white settlers placed it in the Matebeleland region; and mutual intelligibility with the other Shona dialects has virtually been lost.

About six small but significant language groups together account for another 6% of the population, particularly in the two western provinces of Matebeleland North (notably Tonga and Nambya/Dombe) and Matebeleland South (notably Venda and Kalanga), and also in the border areas of Mashonaland (notably Kalanga and Shangani). Other indigenous minority languages are Lilima, Shangwe, Birwa, Tswana, and Lozi in Matebeleland, and Barwe-Tonga (Barwe), Hlengwe, and Chikunda (Kunda) in Mashonaland.

In addition, there are a number of African migrant minority languages, notably Cewa (Nyanja), Sena, Bemba, Sotho, and Fengu, as well as non-African migrant minority languages, notably English, Afrikaans, Portuguese, Hindi, Hebrew, Italian, and Greek. While the distribution of all the indigenous minority languages is regional, that of the African migrant minorities is scattered and is both rural and urban. That of the non-African migrant minorities is scattered but mainly urban, except English, the national official language.

Language Use

An unbalanced bicultural and bilingual situation exists in which English is the high-status language (H), while the indigenous languages are low status (L). At the broad national level, a situation of diglossia obtains in which roles have been assigned as

The two clearly dominant indigenous languages are Shona, spoken by more than 75%, and Ndebele spoken by up to 16%, of the estimated population of 13 million. Both are sometimes referred to as national languages, but that status is only nominal. English, which is the mother tongue of not more than 100 000 people now, is still firmly entrenched as the language of government, business, the media, education, training, and specialized information, as well as upward social mobility and wider communication within and outside Zimbabwe's borders.

As far as the sizes of the speech communities are concerned, Zimbabwe's language situation is less complex than those that obtain elsewhere in Africa, because the two national languages are clearly dominant in their respective areas, where they are also the languages taught in schools and used for limited administrative and judicial functions. Ndebele is dominant in the three western provinces of Matebeleland North, Bulawayo, and Matebeleland South. Shona is dominant in all the other seven provinces of Midlands, Masvingo, Manicaland, Mashonaland East, Harare, Mashonaland North, and Mashonaland West. What this means is that some Shona speakers and Ndebele speakers are not ethnic Shona or ethnic Ndebele. In fact, within the predominantly Ndebele-speaking area, the ethnic Ndebele are actually a minority. The reasons for this are historical and date back to the Umfecane or Nguni dispersal, when various Nguni groups fled from Shaka, the Zulu king. In Malcolm Guthrie's classification, Ndebele is in Zone 40, Group S, along with Zulu, Xhosa, and Swati.

Shona is also in the Southern Bantu group, where it is classified in Zone 10, Group S. The language is a cluster of six dialects, namely Manyika and Ndau in the east, Karanga in the south and midland areas, Kalanga in the west, Zezuru in the central and northern areas, and Korekore in the northeastern area. However, Kalanga has been separated from the rest of Shona for a long time; the white settlers placed it in the Matebeleland region; and mutual intelligibility with the other Shona dialects has virtually been lost.

About six small but significant language groups together account for another 6% of the population, particularly in the two western provinces of Matebeleland North (notably Tonga and Nambya/Dombe) and Matebeleland South (notably Venda and Kalanga), and also in the border areas of Mashonaland (notably Kalanga and Shangani). Other indigenous minority languages are Lilima, Shangwe, Birwa, Tswana, and Lozi in Matebeleland, and Barwe-Tonga (Barwe), Hlengwe, and Chikunda (Kunda) in Mashonaland.

In addition, there are a number of African migrant minority languages, notably Cewa (Nyanja), Sena, Bemba, Sotho, and Fengu, as well as non-African migrant minority languages, notably English, Afrikaans, Portuguese, Hindi, Hebrew, Italian, and Greek. While the distribution of all the indigenous minority languages is regional, that of the African migrant minorities is scattered and is both rural and urban. That of the non-African migrant minorities is scattered but mainly urban, except English, the national official language.

Language Use

An unbalanced bicultural and bilingual situation exists in which English is the high-status language (H), while the indigenous languages are low status (L). At the broad national level, a situation of diglossia obtains in which roles have been assigned as

societal norms to the languages available to the speakers, with English as the H and Shona or Ndebele as the L. In some districts, Shona and Ndebele assume H status against individual minority languages as the L. At the local level within the Shona-speaking community itself, a predominant and generally spoken variety spreading from the capital Harare becomes the H, while the local patois or spoken variety becomes the L. Some speakers are in a trilingual situation, with English as H, (standard) Shona and Ndebele as Mid, and local varieties or minority languages as L. Multilingual situations are also the reason for widespread code switching (*see* **Code Switching and Mixing**) in the speech of most Shona-English and Ndebele-English bilinguals, which is reflective of unequal coexistence of the languages in their society (see, for examples, Ngara, 1982 and Chimhundu, 2002).

Language Policy

There are no accurate or reliable statistics on ethnic groups or language groups in Zimbabwe. There have only been two language surveys conducted, the first during 1929–1931 by Clement Doke covering the Shona-speaking area, and the second by Jerome Hachipola (1998) on the minority languages. Efforts to include questions on language in the last census (2002) failed.

There is no language policy framework in Zimbabwe. As Chimhundu (1997) has observed, the standardization of the nominal national languages is happening without official policy, planning, or legal framework. Successive attempts after independence to have this process formalized through deliberate policy and planning have not succeeded because of lack of political will. At the official level, there also is general neglect of language and cultural issues, in spite of rhetoric about the need to promote and preserve indigenous languages and cultures. Policy on language in education is the responsibility of the Ministry of Education, which, in *ad hoc* fashion, has occasionally come up with directives and guidelines on languages to be taught in schools within the framework of the Education Act of 1987 (Amended 1991; Part XI, para. 55: 225–226). A major consequence of this official attitude is that the indigenous languages have continued to be vernacularized after the attainment of political independence (Chimhundu, 1993), as no serious attention is being paid to the African indigenous languages, in spite of African majority rule.

At the time of writing, there is not even a linguistic normative body in the country. Therefore, officially, no one has the responsibility to oversee the development and standardization of Shona, Ndebele, or any other language in the country. This role now seems to have been assumed by the African Languages Research Institute (ALRI), which was set up at the University of Zimbabwe (UZ) in 2000 in order to institutionalize and expand on the work of the African Languages Lexical Project (ALLEX). Its goal is to research, document, and develop Zimbabwean indigenous languages in order to promote and expand their use in all spheres of life.

Language in Education

Policy on language teaching in the schools is quite confused, although theoretically mother-tongue instruction is available in Shona or Ndebele and/or certain minority languages during the first three years of primary school. Shona and Ndebele are supposed to remain available as subjects at all other levels from the fourth grade, when English should take over as the medium of instruction. However, English is often used for instruction from the very beginning, particularly in former whites-only (Group A) schools and in private (Trust) schools. English is used as the medium of instruction in the whole system of education and training in the country. The latest development is that the Education Ministry has directed that six of the minority languages should be introduced and taught up to grade 7, the final year of primary education, in those areas where the selected languages are predominant. These languages are Shangani, Venda, Sotho, Kalanga, Nambya, and Tonga. At the time of writing, it is not yet clear what is actually happening on the ground.

Literature and Literacy

Published literature in Shona and Ndebele covers a wide variety of genres, ranging from folklore, proverbial lore, and oral poetry to modern novels, anthologies of poetry, plays, and play scripts. This literature is growing, particularly in response to the demands of the high school market, where prescribed texts for literature courses are changed routinely. In theory, there is a sizable market for all these books because of the massive expansion of education in the country after independence, which saw primary and secondary school enrolment increase 10-fold and the educational literacy rate climb from about 45% in 1980 to nearly 80% in 1990. However, the massive expansion of the first decade has not been maintained, and the huge strides that were made then and during the 1990s are being reversed. There have been serious political and economic problems in the country since the parliamentary elections of 2000, which worsened after the presidential elections in 2002.

Everything has been affected adversely, including education, and the literacy rate is definitely falling, although there are no ready statistics on this.

Media

English has continued to dominate in both the electronic and print media, but the use of Shona and Ndebele has increased tremendously on radio and television. In 1990, the percentage usage of the majority language Shona by the Zimbabwe Broadcasting Corporation was 55 on the African language station Radio 2, 49 on the educational station Radio 4, 1.5 on the popular music station Radio 3, and 1 on the general service Radio 1. Around that time, television programs in Shona/Ndebele were very few, with only the daily news summaries and a weekly musical program having regular slots. Only 1.5% of cinema was in Shona, and this comprised mainly films that were oriented toward development and education. The circulation of English-language newspapers such as *The Herald* (135 000 in late 1990) was much higher than that of the weekly *Kwayedza/Umthunywa*, published in Shona and Ndebele (62 365 copies). However, each copy of the latter was read by 10 to 15 people. Even so, its total readership comprised only 1.5% of the newspaper-buying public and 10.7% of the Shona-speaking population.

In the electronic media there have been more radical changes in recent years, particularly in radio broadcasting. Since 2000, there has been an overhaul of the Zimbabwe Broadcasting Corporation and a name change to Zimbabwe Broadcasting Holdings, which continues to maintain a monopoly in broadcasting, although private players are likely to be permitted to operate in the near future. The requirement for 75% local content has opened up more space for the use of Shona and Ndebele on the sole television channel through a mixed bag of programs ranging from local dramas, soaps, sport, news and current affairs, discussion programs, talk shows, and musical shows, as well as raw propaganda. The four radio stations of the corporation have been renamed SFM (formerly Radio 1), Radio Zimbabwe (formerly Radio 2), Power FM (formerly Radio 3), and National FM (formerly Radio 4). There has also been a major policy shift with the requirement that all broadcasting on radio and television should have 75% local content. This has led to a dramatic increase in airtime for local music and in the use of local languages, particularly Shona and Ndebele. Certainly, there have been adverse effects on the variety and quality of programs, as well as a huge increase in partisan propaganda. However, there have been some benefits as well. Attitudes to the indigenous languages have improved tremendously, and the national languages are being used much more in public life and in business. People have gained in confidence and they now participate much more freely in radio and television programs, with many calling in and making their contributions in Shona or Ndebele. Local music is selling much more and the local music industry is doing better than ever before.

Zipf, George Kingsley (1902–1950)

J Van de Walle and K Willems, Ghent University, Ghent, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Zipf was born in Freeport, Illinois, and died in Newton, Massachusetts. He graduated from Harvard in 1924, where he also completed his Ph.D. in comparative philology. During this period, he spent three years in Germany as a student at the Universities of Bonn and Berlin. His Ph.D. was published in 1929. After his return from Germany, he became an instructor in German at Harvard in 1930 and assistant professor of German in 1936. From 1939 onwards, he held the rank of university lecturer. Shortly before his premature death, he published his most important book *Human behavior and the principle of least effort* (1949).

Zipf dedicated almost his entire life to the study of language and human behavior from what he called a 'naturalistic perspective.' According to Zipf, who often refers to the methodology of the exact sciences in his work, language must be studied like any other natural phenomenon. Language constitutes primarily a 'system of behavior' in which words are studied as a set of tools used to convey meanings in order to achieve certain objectives – an extended analogy that Zipf called the 'Tool Analogy.' Zipf showed that language can be understood as a self-regulating structure that evolves independently from other social and cultural factors. Moreover, by striving for optimal communication, language balances two different 'forces.' On the one hand, there is the 'Force of Unification,' which means that speakers minimize articulatory effort by shortening the length of an utterance, leading to an increase in ambiguity. On the other hand, the 'Force of Diversification,' helps hearers want to be able to interpret the meaning of an utterance unambiguously and with the least effort. Fulfilling both requirements leads to a trade-off that Zipf termed the 'Principle of Least Effort.' Language strives permanently for an 'equilibrium state.' But more importantly, since the Principle of Least Effort works primarily on the frequencies of linguistic entities, Zipf was able to introduce a mathematical model that describes the evolution of individual languages, a discipline Zipf (1929) referred to as 'Dynamic Philology.' For this reason, Zipf is regarded as one of the pioneers both of statistical linguistics and synergetic linguistics.

According to Zipf (1949), the Principle of Least Effort is a universal principle that governs all individual and collective behavior of humans; it is the social sciences' analogue of the Principle of Least Action in dynamics.

Zipf's idiosyncratic scientific investigations culminated in several natural laws that he derived for the social sciences and linguistics in particular, the most famous one being known as 'Zipf's law' (though Zipf himself called it the 'rank-size' law; Zipf, 1932, 1935, 1949). It states that the frequency of occurrence of a word (f) multiplied by the rank of this word (r_f), with rank understood as the place this word has in the list of all the words of a text, is constant; in a formula: $f.r_f = constant$ (Zipf, 1929; it should be added that Zipf was in fact not the first to discover this law). Zipf proved that this law not only held for English but also for German, Latin, and Mandarin Chinese, and that it was valid not only for words but also for syllables, phrases, and sentences. Moreover, Zipf's law was found to govern a wide range of social phenomena outside linguistics (e.g., the size of cities, Zipf, 1941) and, since Zipf's death, has even been discovered in a range of other phenomena outside of the social sciences (esp. physics). Therefore, the law is now generally restated in more general terms as follows: the frequency of occurrence of an event (P_r), as a function of the rank (r) where the rank is determined by the same frequency of occurrence, is a 'power-law

Shortly before his premature death, he published his most important book *Human behavior and the principle of least effort* (1949).

Zipf dedicated almost his entire life to the study of language and human behavior from what he called a 'naturalistic perspective.' According to Zipf, who often refers to the methodology of the exact sciences in his work, language must be studied like any other natural phenomenon. Language constitutes primarily a 'system of behavior' in which words are studied as a set of tools used to convey meanings in order to achieve certain objectives – an extended analogy that Zipf called the 'Tool Analogy.' Zipf showed that language can be understood as a self-regulating structure that evolves independently from other social and cultural factors. Moreover, by striving for optimal communication, language balances two different 'forces.' On the one hand, there is the 'Force of Unification,' which means that speakers minimize articulatory effort by shortening the length of an utterance, leading to an increase in ambiguity. On the other hand, the 'Force of Diversification,' helps hearers want to be able to interpret the meaning of an utterance unambiguously and with the least effort. Fulfilling both requirements leads to a trade-off that Zipf termed the 'Principle of Least Effort.' Language strives permanently for an 'equilibrium state.' But more importantly, since the Principle of Least Effort works primarily on the frequencies of linguistic entities, Zipf was able to introduce a mathematical model that describes the evolution of individual languages, a discipline Zipf (1929) referred to as 'Dynamic Philology.' For this reason, Zipf is regarded as one of the pioneers both of statistical linguistics and synergetic linguistics.

According to Zipf (1949), the Principle of Least Effort is a universal principle that governs all individual and collective behavior of humans; it is the social sciences' analogue of the Principle of Least Action in dynamics.

Zipf's idiosyncratic scientific investigations culminated in several natural laws that he derived for the social sciences and linguistics in particular, the most famous one being known as 'Zipf's law' (though Zipf himself called it the 'rank-size' law; Zipf, 1932, 1935, 1949). It states that the frequency of occurrence of a word (f) multiplied by the rank of this word (r_f), with rank understood as the place this word has in the list of all the words of a text, is constant; in a formula: $f.r_f = constant$ (Zipf, 1929; it should be added that Zipf was in fact not the first to discover this law). Zipf proved that this law not only held for English but also for German, Latin, and Mandarin Chinese, and that it was valid not only for words but also for syllables, phrases, and sentences. Moreover, Zipf's law was found to govern a wide range of social phenomena outside linguistics (e.g., the size of cities, Zipf, 1941) and, since Zipf's death, has even been discovered in a range of other phenomena outside of the social sciences (esp. physics). Therefore, the law is now generally restated in more general terms as follows: the frequency of occurrence of an event (P_r), as a function of the rank (r) where the rank is determined by the same frequency of occurrence, is a 'power-law

function' ($P_r \sim 1/r^a$) with the exponent a close to unity (but not necessary 1, as in Zipf's original law). Shortly after his death, Zipf's law attracted the attention of scientists working in the emerging research discipline of Information Theory (Shannon, 1951). The famous mathematician B. Mandelbrot generalized it to $P_r = P_0.(r+\alpha)^{-1/\beta}$, where α and β are constants, assuming that the frequencies of occurrence are determined so as to maximize the number of bits of information transmitted per symbol (Mandelbrot, 1954).

Two main objections have been raised against Zipf's law. The first argues, on mathematical grounds, that Zipf's law is a consequence of the properties of the formulas themselves, indicating that every randomly generated text will inevitably produce Zipf's law (Herdan, 1960; Li, 1992). The second group of objections is based on the argument that Zipf's law is 'linguistically shallow' and misses all the more fine-grained structures of language (Miller and Chomsky, 1963). The debate over the correctness of Zipf's law is still ongoing, and several schools of linguists continue to use Zipf's idea of language as a self-regulating system in their research (see esp. the *Journal of Quantitative Linguistics* and *Glottometrics*).

Zoroastrianism

A V Williams

This article is reproduced from the previous edition, volume 9, pp. 5085–5086, © 1994, Elsevier Ltd.

Zoroastrianism is the ancient religious tradition, otherwise known as 'Mazdaism' or 'Zarathuštrianism,' founded by the Iranian prophet Zarathuštra. Precise dating of Zarathuštra is impossible, but it is widely thought that he must have flourished before 1000 B.C. and probably around 1200 B.C. in the area northeast of present-day Iran. The religion has been transmitted in a faithful form down to the 20th century thanks to the highly conservative priesthood who have maintained both a scriptural and a liturgical tradition of high antiquity. There are currently ~140 000 Zoroastrians in the world, belonging to two language groups: the Persian-speaking Iranian Zoroastrians and the Gujarati- and English-speaking Parsis of India.

The scriptures preserved as supremely holy by Zoroastrians throughout history are the *Gāthās*, 17 metrical 'hymns' composed in an otherwise unattested Eastern Iranian language known as 'Gathic Avestan' (*see* **Avestan**). This is an archaic form of Younger Avestan in which the rest of the Avesta was transmitted orally for centuries and which was eventually

function' ($P_r \sim 1/r^a$) with the exponent a close to unity (but not necessary 1, as in Zipf's original law). Shortly after his death, Zipf's law attracted the attention of scientists working in the emerging research discipline of Information Theory (Shannon, 1951). The famous mathematician B. Mandelbrot generalized it to $P_r = P_0.(r+\alpha)^{-1/\beta}$, where α and β are constants, assuming that the frequencies of occurrence are determined so as to maximize the number of bits of information transmitted per symbol (Mandelbrot, 1954).

Two main objections have been raised against Zipf's law. The first argues, on mathematical grounds, that Zipf's law is a consequence of the properties of the formulas themselves, indicating that every randomly generated text will inevitably produce Zipf's law (Herdan, 1960; Li, 1992). The second group of objections is based on the argument that Zipf's law is 'linguistically shallow' and misses all the more fine-grained structures of language (Miller and Chomsky, 1963). The debate over the correctness of Zipf's law is still ongoing, and several schools of linguists continue to use Zipf's idea of language as a self-regulating system in their research (see esp. the *Journal of Quantitative Linguistics* and *Glottometrics*).

Zoroastrianism

A V Williams

This article is reproduced from the previous edition, volume 9, pp. 5085–5086, © 1994, Elsevier Ltd.

Zoroastrianism is the ancient religious tradition, otherwise known as 'Mazdaism' or 'Zarathuštrianism,' founded by the Iranian prophet Zarathuštra. Precise dating of Zarathuštra is impossible, but it is widely thought that he must have flourished before 1000 B.C. and probably around 1200 B.C. in the area northeast of present-day Iran. The religion has been transmitted in a faithful form down to the 20th century thanks to the highly conservative priesthood who have maintained both a scriptural and a liturgical tradition of high antiquity. There are currently ~140 000 Zoroastrians in the world, belonging to two language groups: the Persian-speaking Iranian Zoroastrians and the Gujarati- and English-speaking Parsis of India.

The scriptures preserved as supremely holy by Zoroastrians throughout history are the *Gāthās*, 17 metrical 'hymns' composed in an otherwise unattested Eastern Iranian language known as 'Gathic Avestan' (*see* **Avestan**). This is an archaic form of Younger Avestan in which the rest of the Avesta was transmitted orally for centuries and which was eventually

committed to writing, probably in the 5th century A.D. The *Gāthās* are a small part of the surviving canon in Avestan, but that too is only a fraction of the original Great Avesta of 21 divisions (Avestan *nask*), which has been lost since the Arab conquest of Iran in the 7th century A.D.

The *Gāthās* are believed to be the inspired compositions of Zarathuštra himself. They are lyrical, poetic dialogues and meditations between the supreme divinity Ahura Mazdā, 'the Wise Lord,' and himself. They are difficult to translate, not least because they are highly condensed in expression and cryptic in metaphorical allusion. Linguistic and content interpretation is helped by comparison with the contemporary Indian *Rig Veda*. The *Gāthās* are arranged according only to their metrical schemes and it is thus impossible to be certain of the evolution of Zarathuštra's thought from a straightforward reading. The prophet's teachings, which inform all the Zoroastrian religion, are moral and ethical in character, with a strong spiritual urgency exhorting humankind to follow divinely created 'truth,' or 'righteousness' (Avestan *Aša*), rather than the demonically created 'lie' (Avestan *druj*). Ahura Mazdā created all good creatures, both spiritual beings (his 'blessed immortals,' Avestan *aməša spənta* and 'worshipful beings,' Avestan *yazata*) and physical creations (humankind, benevolent animals, plants, water, fire, and sky). An entity wholly other than Ahura Mazdā, known as Angra Mainyu 'the hostile spirit,' perpetrates evil in the universe, having invaded it and brought death to the world with his own evil creation of spiritual demons (Avestan *daēva*) and evil physical agents corrupted by him, evil men (Avestan *drəgvant*), the wolf species and noxious creatures (Avestan *xrafstra*). Through worship and through cultivation of the spiritual qualities exemplified in the 'blessed immortals,' men and women may cultivate their own righteousness and thereby help Ahura Mazdā to overcome the forces of Angra Mainyu in the physical world. The religion is strongly eschatological in character, from the *Gāthās* onward, as it looks forward to the complete victory of goodness and wisdom over Angra Mainyu and all his evil brood at a time called 'the making wonderful' (Avestan *frašō.kərəti*). This is a regeneration of the whole cosmos, whereafter evil will have been expelled forever, and it is preceded by a resurrection and last judgment of all souls. In the present time before the end, each soul is judged soon after it leaves the physical state, and according to its accumulation of merit it goes either to a heavenly or to a hellish state to await the final judgment and *Frašōkərəti*. The individual human soul is seen to be directly engaged in the cosmic struggle against evil and the ethos of the religion is one of valiant and active participation in a corporate endeavor for the sake of truth.

The *Gāthās* are enclosed in the manuscripts and in the liturgical rites (Avestan *Yasna*) by the *Yasna Haptanhaiti* ('Worship of the Seven Sections'), which is also in Gathic *Avestan* (*see* **Avestan**). The Younger Avesta comprises liturgical texts and prayers, the *Yašts*, hymns to the *yazatas; Vīdaēvadāta*, 'Law Against the Demons'; *Visperad*, 'Worship of All the Masters'; *Nyāyeš* and *Gāh*, regular prayers; *Xorda Avesta*, prayer book. All these texts, except the *Yašts*, have traditionally been interpreted in the light of the *Zand*, 'scriptural elucidation,' in a Middle Iranian language, Pahlavi (*see* **Pahlavi**). Some lost Avestan texts survive only in their Pahlavi *Zand*. There was originally a *Zand* in the Avestan language and in other Iranian languages, but these were replaced by the imposition of the Pahlavi *Zand* by the last Zoroastrian dynasty, the Sasanians (224–651 A.D.). The Pahlavi books are the principal sources for knowledge of Zoroastrian cosmology and eschatology, mythology, philosophy, ritual, and theology, composed between the 6th and 10th centuries A.D. on the basis of the much older, oral religious tradition and knowledge of the *Avesta*. The main record for Zoroastrian cosmology and religious mythology is the so-called '*Bundahišn*,' 'Creation.' For theology and philosophy, there is the voluminous *Dēnkard*, 'Acts of the Religion,' in seven extant books. Many other smaller texts in Pahlavi survive, most of which have now appeared in scholarly editions and translations.

After the 10th century, Zoroastrians abandoned writing in Pahlavi in a favor of New Persian in Arabic script. The Zoroastrians of Iran were subjected to forcible conversion and oppression by Islam until the 20th century. In the 10th century A.D., a group of the faithful migrated to western India, where they settled and became known as 'Parsis' (i.e., 'Persians'), enjoying religious freedom and material success in trade and, in modern times, in commerce and industry. They adopted Gujarati as their language, and from the 12th century translated the Avestan texts, and some of the Pahlavi texts, into Sanskrit and Old Gujarati. Other texts were transcribed, and hence interpreted, from the cryptic Pahlavi script into the clearer Avestan alphabet: in this form they are known as 'Pazand' texts (literally 'by interpretation'). There is also a group of texts known as the 'Persian *Rivāyats*' dating from the 15th to 18th centuries, which were Irani Zoroastrian written answers to Parsi questions on matters of religious ritual, observance, and morality.

In modern times, the main population center of the Zoroastrian community has been in urban Bombay and, to a lesser extent, Tehran, although

small rural communities do survive in India and Iran. The Parsi and Irani Zoroastrians (the latter since the declaration of the Islamic Republic of Iran) have formed diaspora communities abroad on all five continents. The religion continues to be a mainstay of identity for Zoroastrians, although change in the structure of the community, through education and economic improvement, has brought with it a polarization of 'orthodox' and 'reformist' tendencies into disharmonious sectarian divisions.

Introduction

Zulu, also known as isiZulu, is a Southern Bantu language, and is one of the 11 official languages of South Africa. With over nine million speakers, it is one of the country's major languages, and is used in broadcasting, journalism, and the national and provincial parliaments. Famous as the language of the Zulu empire of the 19th century, it has a growing literature, and there are efforts to develop a technical vocabulary for use in the teaching of mathematics and other sciences.

The language has been the subject of a considerable number of grammatical and linguistic studies, dating back to works of 19th-century pioneers such as Grout (1859). Zulu is closely allied to Xhosa, Swati, and Ndebele, and there is a high degree of mutual intelligibility between these languages, to the extent that it could be argued that they are all varieties of one language, Nguni. The findings of linguistic studies of the other Nguni languages are very frequently applicable to Zulu as well.

Morphology

Zulu displays the typical Bantu morphological features: it is highly agglutinative, and its nouns are divided into various classes, which command distinctive agreement morphology (see 'Syntax' below). Most of the noun classes occur in singular/plural pairs, for example, a noun such as *inja* 'dog' (class 9) will have a plural in class 10, *izinja* 'dogs.' Older studies classified the noun classes according to this pairing (e.g., Doke, 1927), but Canonici (1990) has proposed a classification according to agreement characteristics. From this point of view there are 12 noun classes. There is an elaborate tense and aspect system, and verbs may take valency-changing suffixes (known as 'extensions,' e.g., causative *-is-* in *fund-is-a* 'cause to learn, teach'; passive *-w-* in *fund-w-a* 'be learnt'; reciprocal *-an-* in *fund-is-an-a*, 'teach each other').

The morphology of the language and the semantics of the various grammatical forms have been the focus of linguistic research into Zulu for the past 80 years. Dominating most studies has been Doke's model (1927), which sought to describe Bantu languages in terms appropriate to that family, rather than according to established Latin, Greek, or English terminology. Subsequent accounts have largely been refinements of the Dokean model, e.g., Cope (1984) and Poulos and Msimang (1998).

Phonology

Zulu phonology has been described in a number of works, most notably and comprehensively in Khumalo (1987). Like many Bantu languages, it

small rural communities do survive in India and Iran. The Parsi and Irani Zoroastrians (the latter since the declaration of the Islamic Republic of Iran) have formed diaspora communities abroad on all five continents. The religion continues to be a mainstay of identity for Zoroastrians, although change in the structure of the community, through education and economic improvement, has brought with it a polarization of 'orthodox' and 'reformist' tendencies into disharmonious sectarian divisions.

Introduction

Zulu, also known as isiZulu, is a Southern Bantu language, and is one of the 11 official languages of South Africa. With over nine million speakers, it is one of the country's major languages, and is used in broadcasting, journalism, and the national and provincial parliaments. Famous as the language of the Zulu empire of the 19th century, it has a growing literature, and there are efforts to develop a technical vocabulary for use in the teaching of mathematics and other sciences.

The language has been the subject of a considerable number of grammatical and linguistic studies, dating back to works of 19th-century pioneers such as Grout (1859). Zulu is closely allied to Xhosa, Swati, and Ndebele, and there is a high degree of mutual intelligibility between these languages, to the extent that it could be argued that they are all varieties of one language, Nguni. The findings of linguistic studies of the other Nguni languages are very frequently applicable to Zulu as well.

Morphology

Zulu displays the typical Bantu morphological features: it is highly agglutinative, and its nouns are divided into various classes, which command distinctive agreement morphology (see 'Syntax' below). Most of the noun classes occur in singular/plural pairs, for example, a noun such as *inja* 'dog' (class 9) will have a plural in class 10, *izinja* 'dogs.' Older studies classified the noun classes according to this pairing (e.g., Doke, 1927), but Canonici (1990) has proposed a classification according to agreement characteristics. From this point of view there are 12 noun classes. There is an elaborate tense and aspect system, and verbs may take valency-changing suffixes (known as 'extensions,' e.g., causative *-is-* in *fund-is-a* 'cause to learn, teach'; passive *-w-* in *fund-w-a* 'be learnt'; reciprocal *-an-* in *fund-is-an-a*, 'teach each other').

The morphology of the language and the semantics of the various grammatical forms have been the focus of linguistic research into Zulu for the past 80 years. Dominating most studies has been Doke's model (1927), which sought to describe Bantu languages in terms appropriate to that family, rather than according to established Latin, Greek, or English terminology. Subsequent accounts have largely been refinements of the Dokean model, e.g., Cope (1984) and Poulos and Msimang (1998).

Phonology

Zulu phonology has been described in a number of works, most notably and comprehensively in Khumalo (1987). Like many Bantu languages, it

has an (N)CV syllable structure. There are 40 phonologically distinct consonants, and five vowels. Vowel length is usually predictable, but occasionally distinctive (for example, between the remote past tense and the past consecutive tense: *wa:hamba* 'he/she walked,' *wahamba* 'and then he/she walked'). There is a stricture on the occurrence of two vowels in juxtaposition at surface level, which leads to rules of vowel merging; for example, possessive *a-* prefixed to *inja* 'dog' yields *enja* 'of the dog.' Other processes that have been frequently studied include palatalization and so-called nasal strengthening, where nasals in N + C clusters change the nature of the following C. For example, an aspirated consonant in this position will lose its aspiration, so that the root *phil-* 'live' becomes *-pil-* in the class 9 noun *impilo* 'life.' The language has a high/low tone contrast, and a (derived) high-low tonal cluster may occur on bimoric vowels.

Syntax

Zulu has a basic SVO word order. Relative clauses and possessive phrases follow the head noun, and auxiliaries precede the verb. There is considerable agreement marking, as in the following example, where the affixes glossed as AGR all agree with the class 9 noun *moto* 'car.' ('REL' stands for 'relative marker'.)

Le-y-o	moto	e-n-tsha
DEM-AGR-that	car	REL-AGR-new
o-yi-theng-ile		i-fik-ile.
REL.PERS2-AGR-buy-PERF		AGR-arrive-PERF

'that new car you bought has arrived'

Formal linguistic studies of syntactic phenomena in the Southern Bantu languages have frequently been cast in terms of the Chomskyan Principles and Parameters framework. Much of this work has concentrated on Xhosa rather than Zulu, e.g., Du Plessis and Visser (1992). Little or no work has been done in other frameworks such as Head-Driven Phrase Structure Grammar or Lexical Functional Grammar, although the latter has proved useful in descriptions of other Bantu languages such as Chewa (Nyanja).

Historical and Comparative Linguistics

Like other languages in the east of the Bantu area, Zulu shows fricativization of stops before the 'extra high' vowels of proto-Bantu, which subsequently merged with the high vowels. There is no synchronic operation of Meinhof's law or Dahl's law, and the verbal suffixes (extensions) show no vowel harmony. The noun classes found in the language are (to use the numbering system by which they are known in Bantu studies) 1–7, 9–11, 14, and 15 (the last being used for the infinitive). Only fossilized versions of locative classes remain as adverbs, such as *phansi* 'below.' Unusually for a Bantu language, Zulu has noun suffixes, e.g., the feminine marker *-kazi*. Several of the original Bantu verbal suffixes survive only in unproductive forms (e.g., *-ul-* in words such as *khumbula* 'remember'). The language is well known for its extensive borrowing of Khoi and San words and sounds, noticeably the click consonants in words such as *iqhwa* 'snow.' It has also incorporated many words from Afrikaans and English.

Sociolinguistics

Zulu has certain marked speech forms which are of interest to sociolinguists. An example is *hlonipha*, the speech form traditionally used by married women, who have to avoid words that sound like the names of any of their close male in-laws, and therefore acquire a radically altered vocabulary (see Herbert, 1990). Another example is *isicamtho*, a group-marking variety used by young urban men, which has borrowed many words from English, often with radical change of meaning. There are several distinctive dialects of Zulu, and in some urban varieties the boundaries between Nguni languages have become less marked. In urban areas there is also much code switching between Zulu and the Sotho languages, and between Zulu and Afrikaans or English.

Current Research Directions

Zulu has long been one of the most studied Bantu languages, and it remains a focus of much research in the areas discussed above, and also in new directions including child language acquisition (Suzman, 1996) and computational linguistics (Bosch and Pretorius, 2002).

Zvelebil, Kamil V. (b. 1927)

F Britto, Sophia University, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Kamil Veith Zvelebil was born on November 17, 1927, in Prague, of Czech, German, Jewish, and French ancestry. He received his first Ph.D. in 1952 in Sanskrit, English, and philosophy, and his second Ph.D. in 1959 in Dravidian philology, both from Charles University, Prague. He taught Tamil at Charles University (1960–1965) and was a visiting professor (1965–1966) at the University of Chicago. He emigrated from Czechoslovakia in 1968, after the Soviet invasion, and served as professor at the University of Chicago (1968–1970), and then, after a year at the University of Leiden in Holland, moved to the University of Utrecht, where he worked until his retirement in 1992. He continues his research and writing at present as a resident of France.

A 1998 compilation of Zvelebil's publications lists over 500 entries (Zvelebil, 1998a), most of them dealing with Dravidian languages. His interest in Dravidian matters began in 1951, when he was still a student, and it has continued throughout his life. He has written on a wide variety of Dravidian topics. As he himself asserts, quoting the words of Emeneau, "I did not hesitate 'to publish anything that I might discover, whether . . . literary, linguistic, ethnological, folk tale, or any combination of any of these,' when it concerned Dravidian, particularly Tamil, Kannada, one of the 'tribal' languages of the Nilgiris (Irula), or Dravidian in general" (Zvelebil, 1990: xi).

Zvelebil's major publications may be grouped as follows: (1) Reference volumes that any Dravidian library must have (e.g., Zvelebil, 1973a, 1974, 1990, 1992a, 1994). (2) Religio–philosophical treatises (e.g., Zvelebil, 1973c, 1981, 1992b, 1996, 1998b). (3) Studies on nonliterary cultures (e.g., Zvelebil, 1973b, 1979 and 1982, 1988, 2001). (4) Linguistic and inscriptional studies (e.g., Zvelebil, 1964, 1986, 1998a, 1967 [with Glasov and Andronov], 1970 [with Vacek]). (5) Translations of Tamil, Malayalam, Kannada, Telugu, and Sanskrit works into Czech, Slovak, English, and German (e.g., Iyer, 1990). (6) Reviews of many literary and linguistic books (e.g., Zvelebil, 1985).

Zvelebil's mastery of Tamil language and culture is highly esteemed by Tamil natives themselves, and his publications are remarkable for academic depth, detailed annotations, and extensive bibliography. His voluminous *Lexicon* (1994), written single-handedly, testifies to his extraordinary comprehension of Tamil language and history. His treatises on Murugan and Siddhas are rare masterpieces about the cultural and religious traditions of the Tamils available in English. He is the leading authority today on Dravidian matters, especially on the international scene. He is a pioneer in the field of Nilgiri area studies, having worked at them since 1968, and he is credited with identifying Irula as a separate language.

Zvelebil received the Medaille du Collège de France in 1970, the Josef Dobrovský golden plaque of the Czechoslovak Academy of Sciences in 1992, and was elected Honorary Fellow of the Sahitya Akademi of New Delhi in 1996. He is a member of many learned societies, including the Czech Union of Writers. A number of Zvelebil's articles, which originally appeared in different journals, have been compiled and published by Jaroslav Vacek and Jan Dvořák in two volumes (Zvelebil, 1998a, 2001).

Kamil Veith Zvelebil was born on November 17, 1927, in Prague, of Czech, German, Jewish, and French ancestry. He received his first Ph.D. in 1952 in Sanskrit, English, and philosophy, and his second Ph.D. in 1959 in Dravidian philology, both from Charles University, Prague. He taught Tamil at Charles University (1960–1965) and was a visiting professor (1965–1966) at the University of Chicago. He emigrated from Czechoslovakia in 1968, after the Soviet invasion, and served as professor at the University of Chicago (1968–1970), and then, after a year at the University of Leiden in Holland, moved to the University of Utrecht, where he worked until his retirement in 1992. He continues his research and writing at present as a resident of France.

A 1998 compilation of Zvelebil's publications lists over 500 entries (Zvelebil, 1998a), most of them dealing with Dravidian languages. His interest in Dravidian matters began in 1951, when he was still a student, and it has continued throughout his life. He has written on a wide variety of Dravidian topics. As he himself asserts, quoting the words of Emeneau, "I did not hesitate 'to publish anything that I might discover, whether . . . literary, linguistic, ethnological, folk tale, or any combination of any of these,' when it concerned Dravidian, particularly Tamil, Kannada, one of the 'tribal' languages of the Nilgiris (Irula), or Dravidian in general" (Zvelebil, 1990: xi).

Zvelebil's major publications may be grouped as follows: (1) Reference volumes that any Dravidian library must have (e.g., Zvelebil, 1973a, 1974, 1990, 1992a, 1994). (2) Religio–philosophical treatises (e.g., Zvelebil, 1973c, 1981, 1992b, 1996, 1998b). (3) Studies on nonliterary cultures (e.g., Zvelebil, 1973b, 1979 and 1982, 1988, 2001). (4) Linguistic and inscriptional studies (e.g., Zvelebil, 1964, 1986, 1998a, 1967 [with Glasov and Andronov], 1970 [with Vacek]). (5) Translations of Tamil, Malayalam, Kannada, Telugu, and Sanskrit works into Czech, Slovak, English, and German (e.g., Iyer, 1990). (6) Reviews of many literary and linguistic books (e.g., Zvelebil, 1985).

Zvelebil's mastery of Tamil language and culture is highly esteemed by Tamil natives themselves, and his publications are remarkable for academic depth, detailed annotations, and extensive bibliography. His voluminous *Lexicon* (1994), written single-handedly, testifies to his extraordinary comprehension of Tamil language and history. His treatises on Murugan and Siddhas are rare masterpieces about the cultural and religious traditions of the Tamils available in English. He is the leading authority today on Dravidian matters, especially on the international scene. He is a pioneer in the field of Nilgiri area studies, having worked at them since 1968, and he is credited with identifying Irula as a separate language.

Zvelebil received the Medaille du Collège de France in 1970, the Josef Dobrovský golden plaque of the Czechoslovak Academy of Sciences in 1992, and was elected Honorary Fellow of the Sahitya Akademi of New Delhi in 1996. He is a member of many learned societies, including the Czech Union of Writers. A number of Zvelebil's articles, which originally appeared in different journals, have been compiled and published by Jaroslav Vacek and Jan Dvořák in two volumes (Zvelebil, 1998a, 2001).

Bibliography

Iyer U V S (1990). *The story of my life: an autobiography of Dr. U. V. Swaminatha Iyer.* Zvelebil K V (trans.). Chennai: Institute of Asian Studies.
Zvelebil K V (1964). *Tamil in 550 A.D.: an interpretation of early inscriptional Tamil.* Prague: Oriental Institute.
Zvelebil K V (1970). *Comparative Dravidian phonology.* The Hague: Mouton.

Zvelebil K V (1973a). *The smile of Murugan: on Tamil literature of South India*. Leiden: E. J. Brill.
Zvelebil K V (1973b). *The Irula language*. Wiesbaden: Otto Harrassowitz.
Zvelebil K V (1973c). *The poets of the powers*. London: Rider.
Zvelebil K V (1974). *Tamil literature*. Wiesbaden: Otto Harrassowitz.
Zvelebil K V (1977). *A sketch of comparative Dravidian morphology*. The Hague: Mouton.
Zvelebil K V (1979, 1982). *The Irula (Ëṛla) language* (vols 2 and 3). Wiesbaden: Otto Harrassowitz.
Zvelebil K V (1981). *Tiru Murugan*. Chennai: International Institute of Tamil Studies.
Zvelebil K V (1985). 'Review of David W. McAlpin, Proto-Elamo-Dravidian (1981).' *JAOS 105(2)*, 364–372.
Zvelebil K V (1986). *Literary convention in Akam poetry*. Chennai: Institute for Asian Studies.
Zvelebil K V (1988). *The Irulas of the Blue Mountains*. Syracuse, NY: Maxwell School of Citizenship and Public Affairs, Syracuse University.
Zvelebil K V (1990). *Dravidian linguistics: an introduction*. Pondicherry: Pondicherry Institute of Linguistics and Culture.
Zvelebil K V (1992a). *Companion studies to the history of Tamil literature*. Leiden: E. J. Brill.
Zvelebil K V (1992b). *Tamil traditions on Subrahmanya Murugan*. Chennai: Institute of Asian Studies.
Zvelebil K V (1994). *Lexicon of Tamil literature*. Leiden: E. J. Brill.
Zvelebil K V (1996). *Siddha quest for immortality*. Oxford: Mandrake of Oxford.
Zvelebil K V (1998a). *Tamulica et Dravidica, a selection of papers on Tamil and Dravidian Linguistics*. Vacek J & Dvořák J (eds.) *Acta Universitatis Carolinae, Philologica 3, Orientalia Pragensia XIII*.
Zvelebil K V (1998b). *Ananda-Tandava of Siva-Sadanrtta-murti*. Chennai: Institute of Asian Studies.
Zvelebil K V (2001). *Nilgiri area studies*. Vacek J & Dvořák J (eds.). Prague: The Karolinum Press at Charles University.
Zvelebil K V, Glasov Y & Andronov M (1967). *Introduction to the historical grammar of the Tamil language*. Moscow: Nauka Publishing House.
Zvelebil K V & Vacek J (1970). *Introduction to the historical grammar of the Tamil language*. Prague: Oriental Institute in Academia.

LIST OF ABBREVIATIONS

A	act (in speech act theory); actor (tagmemics); addressee; agent; agentive; argument; author
ABESS	abessive
ABL	ablative
ABS	absolutive
ACC	accusative
ACT	active; actor
Ad	adjunct
ADESS	adessive
ADJ	adjective, -ival
AdjP	adjective phrase
ADV	adverb(ial)
AdvP	adverbial phrase
AFF	affective; affix
AFFIRM	affirmative
AGR	agreement
AGT	agent
AI	Artificial Intelligence
ALL	allative
AM	amplitude-modulated (signal)
Amer	American
AN	adjective precedes noun (in word order typology)
ANIM	animate
ANN	artificial neural network
ANT	anterior
ANTI	antipassive
AOR	aorist
AP	atomic phonology
APG	arc pair grammar
APPL	applicative
ART	article
ASCII	American Standard Code for Information Interchange
ASL	American Sign Language
ASP	aspect(ual)
ASR	automatic speech recognition
ASSOC	associative
ATN	augmented transition network
ATR	advanced tongue root (distinctive feature)

ATTR	attribute
Ausian	Australian Sign Language
AUX	auxiliary
b.	born
BASIC	Basic All-purpose Symbolic Instruction Code
BEN	benefactive
BEV	Black English Vernacular
BNC	British National Corpus
BSE	base-form
BSL	British Sign Language
C	clause; coda (of syllable); codomain (set theory); complement(izer); consonant
c-command	constituent command
c-structure	constituent structure
CA	componential analysis; contrastive analysis; conversation analysis
CALL	computer assisted language learning
CAP	control agreement principle
CAT	category; computer-assisted translation
CAUS	causative
CCG	combinatory categorial grammar
CD	communicative dynamism; conceptual dependency
CF	characteristic frequency; constant frequency
CFG	context-free grammar
CFL	context-free language
CFPSG	context-free phrase structure grammar
CG	categorial grammar
CL	computational linguistics
CLASS	classifier
CN	common noun
COLL	collective
COM	comitative
COMP	comparative; complement(izer)
CONJ	conjunction/conjugation
CONS	consonantal
CONT	continuant; continuative
COP	copula
COR	coronal
CP	complement(izer) phrase
cps	cycles per second
CS	context-sensitive
CSG	context-sensitive grammar
CV	consonant vowel structure/sequence
CV phonology	skeletal phonology
D-structure	deep structure
d.	died
DA	discouse analysis
DAF	delayed auditory feedback
DAG	directed acyclic graph
DAT	dative
DCG	definite clause grammar
DD	discourse domain
DDG	daughter dependency grammar
DECL	declarative
DEF	definite
DEM	demonstrative
DESID	desiderative

DEST	destinative
DET	determiner
DG	dependency grammar
DIM	diminutive
DIR	direction(al)
DIST	distributive
DM	discourse marker
DO	direct object
dp	determiner phrase
DRS	discourse representation structure
DRT	discourse representation theory
DS	deep structure; direct speech
DTR	daughter (in HPSG)
DU	dual
DYN	dynamic
EA	error analysis
EAP	English for academic purposes
ECM	exceptional case marking
ECP	empty category principle
EEG	electroencephalography
EFL	English as a foreign language
EL	elative
ELT	English Language Teaching
EMG	electromyograph(y)
EMPH	emphatic
ENCL	enclitic
Eng	English
equi	equi NP deletion (= identity erasure transformation)
ERG	ergative
ESL	English as a second language
ESP	English for Specific/Special Purposes
ESS	essive
EST	Extended Standard Theory
etym	etymology
EXCL	exclusive
EXIST	existential
EXP	experiencer
F	false (in truth table); formant
f-structure	functional structure
F_0	fundamental frequency
F_1	first formant
F_2	second formant
F_3	third formant
FACT	factive
FDS	free direct speech
FEM	feminine
FFP	foot feature principle
FG	functional grammar
fig.	figure
FIN	finite
FIS	free indirect speech
ff.	*foruit, flourished,* lived
FLA	first language acquisition
FM	frequency modulation
FSP	functional sentence perspective

FSTN	finite state transition network
FUT	future
FUG	functional unification grammar
GB	government and binding (theory)
GB-phonology	government-based phonology
GEN	gender; genitive
GER	gerund
GN	genitive precedes noun (in word order typology)
GPSG	generalized phrase structure grammar
GR	grammatical relation
GS	generative semantics
H	head (of construction); hearer/reader; high/superposed (code/variety, in adiglossic situation); high (pitch/tone)
HABIT	habitual
HCI	human-computer interaction
HFC	head feature convention
HFP	head feature principle
HG	head grammar
HON	honorific
HPSG	head-driven phrase structure grammar
HUM	human
HYPOTH	hypothetical
Hz	hertz
IA	Item-and-Arrangement [model of grammatical description]
IC	immediate constituent
I-E	Indo-European
IELTS	[British Council] International English Language Testing System
iff	if and only if
IGNOR	ignorative
IL	interlanguage
ILL	illative
IMP	imperative
IMPERS	impersonal
IMPERF	Imperfect(ive)
INAN	Inanimate
INCL	Including; inclusive
INCORP	Incorporating
INDEF	Indefinite
INDIC	Indicative
INF	infinitival; infinitive
INFL	Inflection
INSTR	Instrumental
INTERJ	Integration
INTERROG	interrogative
INTRANS	Intransitive
IO	indirect object
IP	inflection phrase; Item-and-process [model of grammatical description]
IPA	International Phonetic Alphabet
IR	inflectional rule; internal reconstruction
IRR	irrealis
IRREG	irregular
IS	indirect speech
ISA	subsumption/subclass 'is a'
IT	Information Technology
ITER	iterative

K	set of situations (in speech act theory)
kHz	kilohertz
KWIC	keyword in context
L	language; low (pitch/tone); low/vernacular variety [in diglossia]
L1	first language
L2	second or foreign language
LAB	labial
LAD	language acquisition device
LARSP	language assessment, remediation, and screening procedure
LAT	lateral
LEX	lexicality (in HPSG)
LF	lexical function; logical form
LFG	Lexical Functional Grammar
lit.	literally
LMC	lower middle class
LOC	local; locative; locus
LP	language planning; linear precedence [statements]; linear prediction
LSP	language for special/specific purposes
LTAG	lexicalized tree adjoining grammar
LU	lexical unit
M	mid [tone]; Middle (in language names); modal
MASC	masculine
Mb	megabyte
MDS	multidimensional scaling
MG	Montague Grammar
MLAT	Modern Language Aptitude Test
MLU	mean length of utterance
MMC	middle-middle class
Mod	modern
MOD	modifier
MRI	magnetic resonance imaging
MT	mother tongue; machine translation
N	new (speaker); noun; nucleus (of syllable)
n.d.	no date
n.s.	new series
NA	noun precedes adjective (in word order typology)
NAS	nasal
NEG	negation; negative
NEUT	neuter
NG	noun precedes genitive (in word order typology)
NL	native language; natural language
NLG	natural language generation
NLP	natural language processing
NLU	natural language understanding
NMR	nuclear magnetic resonance
NN	neural net(work)
NNS	nonnative speaker
NOM	nominative; nominal(ization)
NP	noun phrase
NPrel	relative noun phrase
NRel	noun precedes relative clause (in word order typology)
NS	native speaker
nt	nonterminal
NT	New Testament
NUM	number

NVC	non-verbal communication
O	onset (of syllable)
OBJ	object
OBL	oblique
OBS	obstruent
obs.	obsolete
OCR	optical character recognition
OED	*Oxford English Dictionary*
OOP	object-oriented programming
OPT	optative
OSV	object-subject-verb (in word order typology)
OT	Old Testament; Optimality Theory
OV	object precedes verb (in word order typology)
OVS	object-verb-subject (in word order typology)
P	phrase; predicate
PA	pushdown automation
PART	participle; particle; partitive
PASS	passive
PAT	patient
PERF	perfect(ive)
PERS	person(al)
PET	positron-emission tomography
PF	phonetic form (in principles and parameters framework)
PHON	phonology
PIE	Primitive Indo-European; Proto-Indo-European
PL	plural
PM	phrase marker
Po	postposition
PO	primary object
POL	polite
POSS	possessive; possessor
POTEN	potential
PP	prepositional phrase
PP	past participle
PLUPERF	pluperfect
PRED	predicative
PREF	prefix
PREP	preposition
PRES	present
PRO	an unspecified NP
PRO	pronominal element; pronoun
PROG	progressive
ProgP	progressive phrase
PROHIB	prohibitive
PRESP	present participle
PS-rule	phrase structure rule
PSG	Phrase Structure Grammar
PTQ	[the] proper treatment of quantification [in English] (Montague grammar)
PURP	purpose; purposive
Q	question
QR	quantifier raising
QUANT	quantifier
QU	*wh*-marking
R-expression	referential/referring expression
R-graph	relational graph (in arc pair grammar)

RC	relative clause
RECIP	recipient/reciprocal
REFL	reflexive
reg	regular
ReIN	relative clause precedes noun (in sword order typology)
REP	repetitive
RES	resumptive/result
REST	Revised Extended Standard Theory
rev.	revised
RG	Relational Grammar
RNR	right node raising
RP	received pronunciation
RR	readjustment rule; redundancy rule
RST	Rhetorical Structure Theory
RT	reaction time; RTN recursive transition network
S	point of speech (temporal logic); sentence; sign (sign language); source; speaker; speaker/writer; standard (speaker); strong (syllable); subject (tagmemics); subject term (or conclusion in a syllogism)
S-structure	surface structure
SAE	Standard American English; standard average European OVhorO
SC	small clause; structural change
SD	structural description
SEM	semantics
SGML	standard generalized markup language
SIB	sibilant
sing	singular
SL	source language
SLA	second language acquisition
SLASH	unbounded dependency (in HPSG)
SON	sonorant
SOV	subject-object-verb (in word order typology)
SPEC	specifier
SS	surface structure
SSC	specified subject condition
Sta	statement
STAT	static
STRID	strident
SUBCAT	subcategorization
SUBJ	subject; subjunctive
SUBJUNC	subjunctive
SUBORD	subordinate, subordinative
SUF	suffix
SUP	supine
SUPERESS	superessive
SV	subject precedes verb (in word order typology)
SVO	subject-verb-object (in word order typology)
SYLL	syllabic; syllable
SYN	synonym; syntax
T	tense; text; time; transformation; tree; true (in truth table); tu (= familiar pronoun of address)
T	trace
T-rule	transformational rule
TAG	Tree-Adjoining Grammar
TAL	tree-adjoining language
TBU	tone-bearing unit

TC	total communication [approach] (in schools for the deaf)
TEFL	Teaching English as a foreign language
TEMP	temporal
TERM	terminative
TESOL	Teaching of English to Speakers of Other Languages
TG	Transformational Grammar
TGG	Transformational Generative Grammar
TL	target language
TNS	tense
TOEFL	Test of English as a Foreign Language
TOP	topic(alization)
TRANS	transitive
TRANSLV	translative
TYP	type
U	utterance
UCG	Unification Categorial Grammar
UG	Universal Grammar
UMC	upper middle class
V	verb(al); vowel; "our (= polite pronoun of address)
V	short vowel
V	long vowel
V-form	honorific form (of address)
VFORM	verb form
VIS	visual
VLSI	very large scale integration
VN	verbal noun
VO	verb precedes object (in word order typology)
VOC	vocalic
VOS	verb-object-subject (in word order typology)
VOT	voice onset time
VP	verb phrase
VS	verb precedes subject (in word order typology)
VSO	verb-subject-object (in word order typology)
W	weak (syllable)
WF	word formation
WFF	well-formed formula
WG	word grammar
WH-word	question word (*what*, *which*, etc.)
WP	Word-Paradigm (grammar)
0	zero (covert element)
1	first person
α	alpha, a variable
Σ	sentence; superfoot (in metrical phonology)
σ	syllable

LIST OF LOGICAL SYMBOLS USED

(More specialist symbols are explained in the text)

p, q . . . or P, Q. . .	Variables for sentences or propositions
A, B. . .	Metavariables ranging over sentential or propositional variables
$-$, or $\sim$, or $\neg$	Negation ('It is not the case that . . .')
$\vee$	Disjunction ('or')
&	Conjunction ('and'); 'ampersand'
$\rightarrow$ or $\supset$	Material implication ('if . . . then')
$\equiv$ or $\leftrightarrow$	Material equivalence ('if and only if')
x, y . . .	Variables for individuals
a, b. . .	Singular terms (e.g., proper names)
$\exists$	Existential quantifier ('at least one')
$\forall$	Universal quantifier ('for all')
F, G . . .	Predicates (R, . . . for polyadic predicates)
$=$	Identity
$\Box$	Necessarily
$\Diamond$	Possibly
{ }	Set
$\in$	Set membership
$<$	Less than
$\leqslant$	Less than or equal to
$>$	Greater than
$\geqslant$	Greater than or equal to
iff	If and only if***
wff	Well-formed formula
$\vdash$	Syntactic consequence
$\models$	Semantic consequence

EXAMPLES, TRANSCRIPTIONAL CONVENTIONS, AND THE IPA ALPHABET

Examples

There are many hundred of examples in the encyclopedia. We have tried to be as helpful as we can in indicating to the reader their pronunciation, grammatical analysis, and translation.

Examples from languages normally written with the Latin alphabet are cited in their usual script, including, where appropriate, the appropriate diacritics or special letters, e.g., é å þ ß ł ž Æ Ç İ. Where appropriate, the example may be accompanied by a transliteration or a phonetic transcription.

Orthographic representations of examples from languages normally written in non-Roman script are typically cited in their usual script, but may sometimes be replaced by a transliteration or romanization and may be accompanied by a phonetic transcription.

Languages that have no conventional writing system will, of necessity, be exemplified in transcription, using, wherever possible, the phonetic symbols of the International Phonetic Alphabet (IPA), as described below.

We recognize, however, that it is impossible to be entirely consistent. There are varying conventions in different fields of specialization, and we have not insisted on any deviation from the normal practice of experts, except so far as may be desirable to make the material more accessible to those who are not familiar with the particular field.

Glossing Examples

Examples from languages other than English are normally accompanied by an English translation. With unfamiliar languages, examples are also accompanied by a 'word-for-word' or 'morpheme-for-morpheme' gloss set out in the following manner: the first line is in the original language; the second line, immediately below, is a word-for-word, or, where appropriate, morpheme-for-morpheme, gloss; the last line is the idiomatic English translation. Where words are segmentable, the segments are separated by hyphens, and the corresponding morphemes and glosses are also separated by hyphens (walk-ed: *walk*-PAST). Where words are not segmentable, the glosses are separated by a point (went: *go*.PAST) Glosses are aligned so that the gloss for any word lines up with the word it glosses. Where appropriate, references for cited examples follow the idiomatic translation.

walk-ed	went
walk-PAST	*go*.PAST

mimi-yan-ati-nha
breast-PROP-INCH-PAST
'grew breasts'

nun	'o	fà	male
not	*him*.ACC	*do*.INF	*pain*

'don't hurt him'

swa	se	secg	wate	secgende	wæs	lara	spella:
thus	*the*	*warrior*	*brave*	*teller/telling*	*was*	*of-evil*	*news*

'thus the brave warrior was telling/a teller of evil news' (*Beowulf*, 3028)

Abbreviations for grammatical terms, ACC(usative), INF(finitive), etc., are listed in Volume 14.

Phonetic Transcription and the International Phonetic Alphabet

Transcription is the systematic representation of speech sounds without any reference to how they may be conventionally written. In transcriptions, we follow the usual convention of enclosing phonetic transcriptions in square brackets, e.g., [ɸɯkɯ], and phonemic transcriptions in solidi, e.g., /'fuku/.

We have tried to standardize on the use of IPA notation in phonetic transcriptions. The phonetic symbols used are those of the current edition of the IPA Chart (1993, corrected 1996). A copy is reproduced below, courtesy of

the International Phonetic Association. For further discussion, see the *Handbook of the International Phonetic Association* (CUP, 1999) or the website http://www.arts.gla.ac.uk/IPA/ipa.html.

We have tried to distinguish consistently between potentially confusable pairs of symbols, such as θ and ɵ, ɬ and ɬ, ɣ and ɤ, and have tried to avoid substituting symbols such as Greek *δ* and η for IPA ð and ŋ; we have also tried to avoid symbols that were formerly recognized by the IPA but are now deprecated, such as ʃ for ɨ, ω for ʊ, or ʈ for tʲ. Similarly, we have tried to standardize on IPA ɲ ʃ ʒ ʧ ʤ rather than non-IPA ñ š ž č ǰ (although the latter are of course acceptable in standard orthographic representations or transliterations).

While we standardize on the use of IPA notation, we did not insist on any particular transcription/phonemicization. Nevertheless, unless there was some good reason to the contrary, RP English was transcribed in accordance with the notation found in *Longman Pronunciation Dictionary* (though without syllable spacing and without abbreviatory conventions such as italicized or raised symbols): thus, for example, *hat* /hæt/, *heart* /hɑːt/, *bead* /biːd/, *bid* /bɪd/, *body* /ˈbɒdi/.

Transliteration or Romanization

Transliteration involves the systematic transference of the characters of one writing system into the characters of another, typically into the Latin alphabet (hence romanization). The conventions used for the transliteration of Arabic, classical Greek, Russian, and Chinese are shown below.

Arabic

We have tried to follow Library of Congress rules (http://lcweb.loc.gov/catdir/cpso/romanization/arabic.pdf), but do not underline the digraphs th, kh, dh, sh, gh.

			Vowels		
short		long		doubled	-iyy- (final form: ī)
َ	a	ا	ā	diphthongs	
ُ	u	و	ū	وَ	aw (*not* au)
ِ	i	ى	ī	ىَ	ay (*not* ai)
			Consonants		
ء	ʻ	ز	z	ق	q
ب	b	س	s	ك	k
ت	t	ش	sh	ل	l
ث	th	ص	ṣ	م	m
ج	j	ض	ḍ	ن	n
ح	ḥ	ط	ṭ	ه	h
خ	kh	ظ	ẓ	و	w
د	d	ع	ʻ	ى	y
ذ	dh	غ	gh	ة	-a (in construct
ر	r	ف	f		state: -at)

The transliteration for hamza is a curly apostrophe or right single quotation mark (’) and that for ghain a reversed apostrophe or left single quotation mark (‘). We have tried to avoid a straight apostrophe (ˈ), raised c (ᶜ), and other substitutes.

Ancient Greek

Vowels and consonants			
α	a	ν	n
β	b	ξ	ks
γ	g	ο	o
δ	d	π	p
ε	e	ρ	r
ζ	z	σ, ς	s
η	ē	τ	t
θ	th	υ	u
ι	i	φ	ph
κ	k	χ	kh
λ	l	ψ	ps
μ	m	ω	ō

Diphthongs, digraphs			
αι	ai	αυ	au
ει	ei	ευ	eu
οι	oi	ου	ou
υι	ui	ηυ	ēu

Capitals (Α Β Γ Δ . . .) are transliterated as the corresponding roman capitals (A B C D . . .). Rough breathing: h. ῥ = rh. Smooth breathing is ignored. Long α ι υ are generally shown as ā ī ū, and ᾳ ῃ ῳ as āi ēi ōi.

Accent marks are generally ignored unless essential: ά, ὰ, ᾶ = á, à, â. A vowel with a circumflex accent is necessarily long, so is not given a length mark; an acute or grave accent may be combined with a length mark if necessary (ᾱ́).

Proper names are usually Latinized in the usual way: Dionysius Thrax (not Thrâiks).

Russian

а	a	л	l	ц	ts
б	b	м	m	ч	ch
в	v	н	n	ш	sh
г	g	о	o	щ	shch
д	d	п	p	ъ	˝
е	e	р	r	ы	y
ж	zh	с	s	ь	ˊ
з	z	т	t	э	ė
и	i	у	u	ю	iu
й	ĭ	ф	f	я	ia
к	k	х	kh		

We have tried to follow Library of Congress rules (http://lcweb.loc.gov/catdir/cpso/romanization/russian.pdf), but do not put a tie bar over ts, iu, ia. Uppercase letters (АБВ. . .) are transliterated as the corresponding Roman capitals. ё = ë. Established English forms may be used where appropriate: *Yeltsin*, not *El’tsin*.

Chinese

The Pinyin romanization of Chinese is generally used. Tone marks are included or omitted at the author’s discretion. If Wade-Giles or some other romanization is necessary (e.g., in proper names normally so cited), then at the first use there will be an accompanying Pinyin version.
